# Lettsomian Lecture

ON THE

# PLES OF TREATMENT IN RELATION TO DISEASES OF THE NERVOUS SYSTEM.

*ing the Third Lettsomian Lecture[*] in 1926, delivered before the Medical Society of London on March 15th*

BY E. FARQUHAR BUZZARD, M.D. OXF.,
F.R.C.P. LOND.,
PHYSICIAN TO ST. THOMAS'S HOSPITAL.

226

IN the two previous lectures I have been chiefly ncerned with principles governing treatment in rious diseases of the nervous system in which ructural defects of the brain and spinal cord, turally accompanied by striking departures from eir normal function, are outstanding features. In ew of the limitations to repair which are inherent highly specialised nervous tissues, it has often en necessary to content myself with the considera- n of measures, either frankly preventive in nception, or favouring a process of physical or ychological adaptation to permanently altered nditions.

It is now my purpose to discuss governing principles relation to conditions in which disorders of function, ssibly accompanied by physical or chemical changes yet unexposed, command our attention. Prevention d adaptation must again receive their due, and both ust largely rely for their efficacy on anticipation, well as early recognition of morbid symptoms.

The prevention of head injuries, although a matter uch gravely concerns the League of Nations and mperance societies, can hardly be reckoned among r professional duties, but the prevention and treat- ent of the effects produced by head injuries are sponsibilities with which we are frequently faced d which we cannot shirk. The results of blows flicted on the cranium are, especially in their mediate consequences, too numerous and various r general consideration now, even were I disposed courageous enough, which I am not, to trespass on field of surgery so thoroughly explored by Mr. Wilfred otter. The subject is one, however, which may be proached from another direction by a physician ho is sometimes called upon to deal with the remote fect of such injuries, and who, rightly or wrongly, inks that they are often avoidable.

### PROPHYLACTIC IMPORTANCE OF REST AFTER CONCUSSION.

The particular type of head injury with which I am ncerned to-night is that in which a blow on the anium results in a period of unconsciousness, short r long, unaccompanied by any serious defect in the ones of the skull. Such events are very common in ery-day life, and all doctors must meet many xamples of them in the course of their practice. he period of unconsciousness is attributed to con- ussion, and its importance as evidence of injury o the brain is often too lightly assessed compared ith the attention paid to a fracture of the skull. But it must be remembered that the brain is a very elicate, and sometimes important, organ, whereas he cranial bones only serve a useful purpose in that hey help to protect the brain from direct injury.

My purpose in raising the question of the treatment f head injuries will be best served by the description f some typical although fictitious cases :—

> A man is thrown from his horse, landing with his head on hard ground. He lies motionless and unconscious for a few seconds or minutes, picks himself up, feels dazed, but, in spite of a certain amount of headache, manages with or without assistance to reach his home. He feels a bit shaken next day, but his headache is less severe, and he naturally expects to be well again very soon. As a matter of fact, he finds that his expectations are not fulfilled, and hardly a day passes without some hours of headache, generally brought on or increased in severity by exertion, mental or physical, by fatigue or excitement. The headache is either of the bursting character, especially in the early stages, or, later, is described as pressure on the vertex or tightness round the temples. Before very long the patient becomes anxious, irritable, lacking in concentration and decision, complains that his memory is at fault, that he cannot sleep, and that he thinks at times that his mind must be giving way. His condition can be best described as that of post-concussional headache complicated by anxiety neurosis.

This miserable state would have been prevented had the patient gone straight to bed, remained at complete rest for a period proportionate to the severity of his injury, and only resumed the activities of life by carefully graduated steps.

The difficulties experienced in carrying out this preventive treatment are often provided by the patient, who either refuses to regard his accident as in any way serious or who, having been X rayed and assured that there is no fracture of the skull, takes no interest in what may have happened inside it. Judging from one's own experience, it is probable that at least another 50 years will elapse before the lay mind is sufficiently educated to realise that the soft structures within the cranium are of more functional importance than their osseous envelope. Possibly this prophecy might be falsified if the profession not only recognised such an obvious truth, but consistently and firmly used it as the basic principle of their practice.

How long a period of complete rest should be insisted on is a question not easily answered. During the war, when many of such patients were under military discipline, I saved myself a lot of trouble, and the victims of head injuries, such as we are describing, much suffering by ordering as a routine measure a month in bed for each case. In civil practice this is not possible, and the amount of rest may be reasonably regulated by taking into account the extent of amnesia, especially of the retrograde variety, disclosed by the patient, and also the severity of the symptoms immediately following the accident, the period during which he was dazed, confused, or exhibited the symptoms which we place under the category of cerebral irritation. In any case, the resumption of activity should be gradual, and can be usefully employed as a test for the adequacy of the rest which has been enforced. There can be no other alternative treatment, and its simplicity is its chief and only objection. As an adjunct a dose of bromide, 10 or 15 gr., should be given twice daily, partly in order to allay restlessness and depression, partly as a prophylactic measure against possible epileptic tendencies. It is even desirable that this medicinal precaution should be persevered with for some months after active life has been resumed. May I add that the success of the treatment I have outlined is much more likely to be achieved if the patient is taken into the confidence of the doctor and is frankly told that the measures are necessary, not so much for symptoms which are present, but in order to prevent months of suffering in the future.

We have yet to consider the treatment of the patient who has neglected or failed to seek advice for weeks or months after his injury, and who comes for assistance in the condition I have described as that of post-concussional headache complicated by anxiety neurosis. Quite briefly he will require rest in bed, more lengthy and perhaps more secluded than that already referred to, the administration of suitable sedatives and analgesic drugs, and the application of psychotherapy appropriate to his individual anxiety or anxieties. For it must be remembered that the psychological picture may by this time have become complicated by additional complexes, even by some, perhaps, of sexual complexion.

---

[*] Lectures I. and II. appeared in THE LANCET of Feb. 20th and March 6th respectively.

### "CONTUSION HEADACHE."

May I now remind you of another not uncommon sequel to a comparatively slight head injury, the pathology of which has been lucidly expounded to this Society within recent times by Mr. Trotter.[1] In contrast to the concussion effects just described, this variety has been sometimes referred to as "contusion headache." A contusion headache may occur as a separate entity, but not seldom it complicates the concussion picture so that we find a patient suffering from both conditions at the same time.

Let me take for consideration an uncomplicated example. A man receives a blow on the head from a weapon or missile which hurts and perhaps dazes him, but produces no concussion, no loss of consciousness. Not unnaturally he suffers from a headache which persists for a short or long period but which clears up leaving him apparently none the worse for his injury. The skull may or may not have been cracked by the blow, but there is no evidence of a depressed fracture indicating the necessity for immediate operation. In fact, the outward and visible signs of trauma may be limited to a local bruise. The patient soon resumes his ordinary duties, but finds that he is subject to severe headaches, more or less localised to the site of injury and associated with coincident, and, perhaps, extreme, tenderness of the scalp in its neighbourhood. These bouts of pain are clearly excited by physical exertion, especially such forms as entail stooping or rapid changes of cranial position. The pain is generally described as like toothache in character, and each bout is often of not more than a few hours' duration. Their frequent recurrence and severity are, however, sufficient, as time goes on, to interfere very seriously with the patient's activities and pleasures; not infrequently they give rise to mental disturbances amounting to maniacal outbursts or melancholic depression. In some cases a period of complete rest may suffice to give relief, especially if it is resorted to at an early date. In others rest fails to bring about the desired result, and an operation is the only measure calculated to cure the patient of his suffering and, perhaps, to save his reason. The operation is a simple one, as its objective, according to Mr. Trotter, is to decompress at the site of injury and so to establish a more normal circulation in the bruised tissues which are exposed to view by the opening in the skull. Resolution, long delayed, takes place, the headaches cease, and, if thought desirable at a later stage, the gap in the bone may be closed by a bone graft or other mechanical means.

The principles governing the treatment of minor head injuries are so simple and, in the eyes of those ignorant of their sequelæ, so superfluous that they are frequently neglected. Their importance from the point of view of prophylaxis is far-reaching and, in particular, extends to the subject to which I now propose to draw your attention.

### TRAUMATIC NEURASTHENIA.

It is not a far step from head injuries to traumatic neurasthenia, and, in considering the latter, what has been said of the former must necessarily be kept in mind. I make no apology for bringing forward this subject, or, indeed, for reiterating the views I have before expressed in connexion with it, as there is no problem in medical practice about which more misunderstanding and confusion of thought and speech have long prevailed. Nor does this fog beset only the minds of doctors; it exercises a bewildering influence on the mind of the public, and above all on the matter-of-fact and unimaginative mentality of the legal profession. To listen to the cross-examination of medical witnesses on the topic of traumatic neurasthenia in a court of law can only be compared to being present at the performance of a farce, a comedy, and a tragedy combined in one play, and it is difficult to say whether its humour or its pathos makes the more appeal.

In order to arrive at some principles for our guidance in the prevention and treatment of traumatic neurasthenia, it is essential to form a clear conception of neurasthenia and of its causal relationship to trauma. Experience teaches us that the term is applied chiefly to two large groups of cases, both of which present almost constant clinical characteristics. The first group comprises patients who have sustained an injury to some part of the body, more frequently but not necessarily the head, of varying severity. They present the picture which we commonly associate with an anxiety neurosis, the only difference being that they attribute all their troubles to the injury. They complain of constant "pressure" headache, insomnia, loss of energy and ability to concentrate, of giddiness, tremors, and fears, as well as of pain and tenderness at the site of injury, be it the foot or the head. Their appearance is one of misery and apprehension, but the most careful examination reveals no evidence of organic disease. The second group is of smaller dimensions. Its members walk into your room leaning forward on a stick grasped in one hand with the other placed over the lower part of the back. You know at once that the site of injury, a strain or a blow, is the spine. In many cases the real origin of the trouble is a sharp attack of lumbago coming on acutely, as it often does, while making some physical exertion. These patients, like those of the first group, may present symptoms of anxiety, and complain bitterly of pain and tenderness over the spinal column and neighbouring muscles. Examination, again, reveals no evidence of organic disease.

There are two points in connexion with both these groups of cases which we cannot afford to overlook. The neurasthenic symptoms are not the monopoly of patients who have sustained injuries to the head or even to the spine; a serious obstacle to the belief that they are produced by physical disturbances in the nervous system. On the other hand, it is not unreasonable to suppose that the awe with which an injury to the skull or spine is popularly regarded may suffice to account for the frequency with which such injuries are followed by the development of an anxiety neurosis. In the second place there is no constant relationship between the severity of the trauma and the incidence of the neurotic sequelæ, but it is not without significance that injuries resulting in total disablement, such as a fractured limb, are rarely complicated by the anxiety features of traumatic neurasthenia.

On what does the incidence of neurasthenia as a sequel of trauma depend? No doubt some part must be played by the mental make-up of the patient. An inherent mental instability must be regarded as a factor which cannot be overlooked, but it cannot be blamed in all cases, and we must look elsewhere for a more important determining cause. Reviewing accidental injuries and their consequences generally, it is impossible to avoid the conclusion that the factor common to the great majority of cases of traumatic neurasthenia is the knowledge that the responsibility for the trauma can be placed on shoulders other than those of the victim. The responsibility falls on the employer, on a corporation such as a railway company, or on the State. Traumatic neurasthenia is rarely met with among persons the responsibility for whose injuries cannot be relegated elsewhere, although, as I have already pointed out, a neurasthenic state is not an uncommon sequel in cases of neglected concussion.

But while laying most emphasis on the part played by responsibility, there are other factors which contribute in many cases to the development of the anxiety neurosis. May I take the liberty of quoting some passages from a former paper of mine in order to illustrate how the handling of these cases in their early stages influences their course and prognosis, and to lay stress on certain principles of preventive treatment?

---

[1] Transactions, vol. xlvii., p. 270.

"Smith is injured in an accident occurring in the course of his employment. The accident took place in such a way that it caused a considerable emotional disturbance—that of fear. This is often called shock, but is distinct from surgical shock. The injury caused pain, and the doctor, on examining him, said: "By Jove, you have had a narrow squeak: an inch to the left and the blow would have broken your back." A restless night, during which he remembers that there were only three men doing what ought to have been done by four. This gives rise to the sense of injury. His employers are responsible for his suffering. A mate comes to see him a day or two later, and reminds him that Jones had a somewhat similar accident and was dead within a year. (It is immaterial from their point of view that Jones died of influenza and pneumonia.) His wife is a plucky woman and sympathetic, and also much incensed against the employers because of the neglect to supply sufficient labour for the job. She makes him comfortable at home, in spite of shortened means. His injury is really slight, and after going to the hospital or his doctor twice a week for two or three weeks, there is no physical disablement. But the seeds which were planted have grown, and will continue to grow, with the result that you soon have a condition of anxiety neurosis in full bloom. If the doctor said he had had a very narrow squeak, it is obvious that he must have been very seriously injured, and he could not be well in a month. Even if he appeared well there was always the possibility that something else would develop. Did it not in the case of Jones? It must be remembered that to the lay mind trauma is still the most important and universal ætiological factor in medicine, just as it was in medical text-books 50 years ago. A pain here or a pain there is sufficient to keep him on the alert for complications and sequelæ. Fear and anxiety keep him awake at night, and so the vicious circle is formed. Beneath the surface all the time is the knowledge that his employer was responsible for making him ill, and is still responsible for getting him well. Yes, he will go into hospital for treatment, but under protest. He will come out of the hospital worse than he went in, and more convinced thereby that the injury he received was far more serious than other people, particularly the insurance officers, realised. Weeks, months, and, perhaps, a year or two pass by. He has either become incurable, or is tempted by a lump sum of money in full compensation for all his claims. Accepting this, he has unwittingly resumed responsibility for his health, and sooner or later health is restored to him.

The case of Mr. Robinson, however, is rather different.

He was in a train returning from business when a collision occurred. He was thrown across the carriage and considerably bruised, and not a little frightened. What with his bruises and fright he had several restless nights, in the course of which he explained to his wife the dastardly neglect of the railway company in allowing an hour to elapse between the collision and his being conveyed to a place of safety. This indignation grows as his bruises and fright disappear. He feels disinclined to return to business, and his doctor has hinted that two or three weeks at the seaside in order to get over the "shock" are advisable. After all the company must pay for this, and it is a long time since he had a good holiday. On his return he is not yet inclined to work, and, meanwhile, the question of how much compensation is due to him has become, and is still, a matter of dispute between his and the company's lawyers. He is given to understand that he is suffering from traumatic neurasthenia, and it is impossible to say when anyone may recover from that disease. Anyhow, the company is responsible not only for the disease, but for financing him until he is well. Litigation threatens, further medical examinations ensue, a sum is offered; shall he accept it? More sleepless nights, and the picture of anxiety neurosis, complicated by the sense of injury, is complete.

Now let us look for a moment at the other side.

A hunting man sustains a severe concussion as the result of a fall. His doctor tells him that he was within an ace of breaking his neck. He has nobody but himself or his horse to blame, and accepts the medical dictum in the spirit that a miss is as good as a mile. After a few days' rest he is feeling so much better that he wants to know when he may get up, and how long it will be before he can hunt again. Provided he is kept long enough at rest there will be no neurasthenia. If, on the other hand, he is up too soon, headaches will develop, and he will find he is very easily tired and quite unable to concentrate. A further period of rest would get rid of these symptoms, but neglect of such precautions would probably mean the establishment of a neurasthenic state from which recovery may be slow.

A consideration of these stories provides us with a wholesome warning in regard to what is better left unsaid when dealing with a patient immediately after he has been injured, and should indicate the kind of psychotherapy which can be advantageously practised in the course of subsequent attendance. It serves also to illustrate the profound part played by the patient's sense of injury towards those whom he deems responsible for his suffering, an attitude which has been fostered in some instances, no doubt, by the more permanent feeling associated with class distinction. This sense of injury forms one of the chief obstacles in the path of successful treatment. There is a wrong to be put right, and, until this has been done to the satisfaction of the wronged man, he is not likely to turn his attention away from his injury to the ordinary affairs of life.

If the views I have expressed concerning the pathogenesis of traumatic neurasthenia are accepted, our business is to exercise an intelligent anticipation of its early signs, with a view to checking further developments. When the condition is established, we must not underestimate the difficulties in the way of successful treatment, least of all that which concerns responsibility; it has already been recognised to some extent in the admission often made that the first step towards a patient's recovery would be the settlement of his claim. This admission is generally interpreted as evidence of what might be expected from the satisfaction of a greedy desire. I venture to think that the shifting of responsibility for the patient's recovery on to his own shoulders plays at least as important a part in the subsequent history of the case.

### MODERN PSYCHOTHERAPY.

It is with great diffidence that I approach the subject of psychotherapy, a diffidence based on my ignorance of many of its various doctrines and of the meaning of many of the technical terms which are employed by those who practise it. I am old enough to suspect that the personality of the psychotherapist is of more importance than the doctrine on which he bases his treatment; I am young enough to be sure that concealed in the terminological maze of modern psychology there are many substantial truths which are destined to find their way out and to receive in turn the recognition they deserve. Even as it is, in spite of much abuse, deserved and undeserved, in spite of much partial and impartial criticism, the advances which have been made in the practice of psychotherapy during the last 25 years compare favourably with any advances in other branches of medicine. Although the whole subject is still in its scientific infancy, and still unable to control its emotional tendencies, the time has come when it might be profitable to consider, and perhaps to define tentatively, the scope of psychotherapy. In the course of these lectures, I have made it clear that, in my view, psychotherapy, using the word in its widest sense, is an essential factor in the treatment of all patients suffering from organic disease, and that, for our professional reputation's sake, we should be careful to recognise and acknowledge, at any rate to ourselves, what we owe to it and what to other remedial measures, for any successes we may attain. But psychotherapy, using the word in its more technical and specific sense, is a branch of practice concerned chiefly with the treatment of so-called functional, but better-called mental, disorders, and it is my purpose this evening to discuss its comparative value in this relationship. The ethical aspects of psychotherapy, especially in relation to psycho-analysis, have received perhaps as much attention as they deserve, and have been the theme of many blood-curdling and sometimes mirth-provoking stories. Perhaps for this reason the profession has been left a little confused in its ideas as to the efficacy of this method of treatment in different forms of mental disorder.

In order to clear the deck, as it were, for further discussion, we may agree, perhaps, that all patients whose symptoms are frankly hysterical are fit subjects for the art of psychotherapy in the forms of suggestion, education, or investigation. The same remark applies with equal force to patients suffering from an anxiety neurosis, but this brings us without further delay to a position in which there is certainly much confusion of nomenclature and probably a widespread want of clear thinking. I find, for instance, that it very rarely occurs that a patient is sent to me with the diagnosis of "anxiety neurosis," and that never does one come with the diagnosis of manic-depressive psychosis. Both groups of patients arrive with the label of "neurasthenia" hung indiscriminately round their blushing necks. This sounds like a terrible indictment of professional knowledge, but it can be made without hesitation and even without fear of contradiction.

How many doctors realise that among their neurasthenic patients are a number of examples of the milder forms of the manic-depressive psychosis? How many doctors realise that these are the "neurasthenics" who wear their patience to its last thread and yet invariably recover? One more question. How many doctors and how many of these patients themselves realise that the treatment prescribed has had nothing to do with their recovery?

Let us consider the last question first. The depressive is a patient who invariably recovers, provided he is protected from suicide, but it is beyond our ken to say when the recovery will take place. Naturally the person who is in attendance at the time of recovery will receive credit which is not his due. Doctors, quacks, and faith-healers share in the distribution of this bonus. Sometimes the patient, when depression again overtakes him, has resort to the doctor or quack who cured him before, but he soon realises that this time the same treatment is ineffectual, and further experiences of similar character generally convince him that his recoveries have been spontaneous.

The other two questions are only concerned with diagnosis, a subject intimately connected with the principles governing the practice of psychotherapy. The depressive patient differs from the patient with anxiety neurosis in many ways, but the diagnosis is not always easy unless a careful history is taken. From the latter we may learn of one or more earlier attacks of depression and that, in the intervals, the patient is often more energetic, more cheerful, and even less anxious and responsible than the normal. The attack of depression may have no apparent cause or may be preceded by a period of overstrain. The gloom is deep, varies little in intensity, and is often associated with much self-reproach for particular misdeeds in the past or with a general sense of inferiority. The patient is less concerned with his physical condition than with his mental misery, although he may lose weight and suffer from dyspepsia and constipation. Probing into his troubles only makes him worse, and is often a dangerous procedure capable of driving him to suicide. It is impossible for him to believe that he can get well and he loses all interest. He takes his food without relish, takes walks without enjoyment, and can derive pleasure from nothing. The only comfort of which he is sensible is the sympathetic encouragement and the patient hearing he receives from his doctor or his nurse, and yet neither gives him real relief.

These are the chief characteristics which distinguish the manic-depressive from the anxiety neurotic, and the diagnosis is a matter of great importance in regard to treatment. The manic-depressive is made worse by any form of systematic psychotherapy involving mental probing and investigation. The anxiety neurotic cannot be cured without the employment of some such method of treatment. The only psychotherapy permissible for the depressive patient is the sympathetic encouragement and the daily audience of his woes to which I have already referred. Add to these the provision of a sufficiency of rest, food, and sleep and the list of measures known to us, which will ensure the patient a safe passage through his period of misery, is complete.

Lest there should be any misunderstanding let me say at once that my remarks have reference only to the milder forms of the manic-depressive disorder, not to the severe forms met with in asylum practice. But these patients are very numerous; they infest our consulting-rooms and the out-patient departments of hospitals; they mingle with us socially, and we count many of them among our more moody friends. Great is the power of a name! I cannot help thinking that, had this form of mental disorder carried any less ugly designation, its character would ere now have been more generally recognised and its diagnosis more frequently arrived at. But it goes against the grain to call even one's worst enemy a manic-depressive, and it is high time that a less opprobrious epithet is found for patients who sometimes command our respect and affection as well as our sympathy.

Time will not permit me to discuss at length the principles governing the use of psycho-analytical methods in relation to all functional disorders, and I shall content myself with referring very briefly to only one or two. The compulsion neuroses and the phobias are examples of disorders which are frequently dealt with on these lines and which respond to such treatment in various ways. Many cases of phobia certainly receive benefit and some are permanently cured; rarely does any harm result. Patients suffering from compulsion neuroses, on the other hand, are less certain quantities, and it is probable that faults in the technique of analytical methods may be responsible for some disastrous results following their employment, and that experience will eventually teach us how the technique can be improved so as to ensure more universal success. A question which has interested me for a long time is whether spasmodic torticollis is a functional disorder, in the sense that it can be cured by any psychotherapeutic measures, and I am bound to confess that it has not yet been answered to my satisfaction. So obstinate is it to all other methods of treatment that further efforts on psycho-analytical lines should be encouraged so long as evidence of harmful results is not forthcoming. The occupation neuroses may, perhaps, be placed in the same category, although I entertain grave doubts whether in a severe case of writer's cramp, for instance, any cure is possible in the sense that the patient can return with impunity to his scriptorial excesses.

As a preface to my first lecture I referred to the professional success enjoyed by John Coakley Lettsom 150 years ago, and suggested that his success must have been founded largely on his personality and on empiricism. The art of medicine has advanced far since his day, and personality, always to some extent an inherent and intangible gift, can be cultivated in suitable soil by the study of modern psychology; empiricism is rapidly giving place to more scientific measures. In the course of these lectures I have insisted on the value of being guided by certain principles in the treatment of patients suffering from diseases of the nervous system, and have chosen, by way of illustration, the simpler and more common rather than the more intricate and rarer problems with which we are confronted. In these days we are all, practitioners and students alike, appalled by the ever-growing mass of facts and theories in which the art of medicine is becoming involved, and by the hopelessness of attempting to keep pace with advances in all its branches. It is inevitable, therefore, that we must each of us turn more and more for guidance to principles which are based on sound physiological, psychological, and anatomical foundations, and that the student of to-day and of the years to come should never fail to master these even at the expense of much detailed knowledge of disease. On such foundations the knowledge of disease is easily built up; without them no wealth of experience can ever produce the type of medical man who will lift the profession above rivalry with quacks to a position in which it may secure and hold the trust and confidence of the public.

### ON

# EXPERIMENTAL EPIDEMIOLOGY.

*Delivered before the Royal College of Physicians of London on March 9th*

BY W. W. C. TOPLEY, M.D. CAMB.,
F.R.C.P. LOND.,
PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF MANCHESTER.

IN the previous lectures it has been shown that it is possible to initiate an experimental epidemic among mice, and to maintain its activity for an apparently unlimited period of time. Is it possible to modify the course of events in the opposite direction, to alter our experimental conditions in such a way that an epidemic fails to develop after we have brought together the parasites and their hosts, or to intervene after a wave of mortality has commenced its rise and bring about its premature fall?

## THE EFFECT OF DISPERSAL.

In the experiments on the initiation and maintenance of epidemics it was found that the numerical relation between infected and susceptible mice, and the rate of immigration of the latter, exerted a decisive influence on the mortality-rate. It was natural to inquire whether any form of redistribution of the population at risk, carried out after the initial admixture of infected and susceptible animals, would prevent the occurrence of a wave of mortality, or bring to an early close an epidemic that had already developed a high death-rate.

Two experiments on these lines have been completed. In each case the infection studied has been mouse-typhoid, and the redistribution has consisted in the dispersal of the population at risk into smaller groups housed *in separate cages*. In the first experiment of this kind,[5] which is recorded in Chart 12, the dispersal was carried out during the pre-epidemic phase On the day when the experiment commenced, 305 normal mice were added to 24 survivors from an earlier epidemic. During the following week there were 15 deaths. Of these, 11 occurred among the normal mice and four among the presumably infected animals. Seven of the dead mice were eaten, seven were examined post mortem with negative results, while one of the survivors, which died on the sixth day, was found to have succumbed to typical mouse-typhoid. On the eighth day redistribution was carried out; 294 of the added mice were then alive. Of these, 100 were placed in one large cage; 94 were dispersed into four groups, three of 25 and one of 19 mice; 100 were dispersed into ten groups, each of ten mice. The mortality was observed for the following 68 days. On the sixty-ninth day the survivors from each of the two dispersed herds were re-aggregated in a single cage, and the course of events was watched for another 93 days. Chart 12, which gives the daily percentage of survivors for each of the three herds, carries the record to the 120th day of the experiment. In the undispersed herd the epidemic developed rapidly, and had run its course by the sixty-eighth day, when the survivors numbered 5 per cent. of the original population. The herd, which was dispersed into four groups, derived no significant advantage from this dispersal: 9·6 per cent. remained alive on the sixty-eighth day. The herd which was dispersed into ten small groups suffered a far lower mortality; on the sixty-eighth day the survivors from this herd amounted to 55 *per cent.* of the mice originally at risk. In the period which followed re-aggregation this herd suffered further loss. It will be seen from the chart that the curve recording the daily $l_x$ values continues its downward course; indeed this curve, from the tenth day of the experiment *onwards, approximates closely to a straight* line. When the experiment terminated, on the 161st day, the survivors from the undispersed herd numbered 2 *per cent., from the herd divided into four groups* during the period of dispersal they numbered 2·1 per cent., from the herd dispersed into ten small groups *they* numbered 24 per cent. These figures give the total mortality. The specific mortality, which excludes those deaths in which no evidence of enteric infection was found post-mortem, was 87 per cent. in the undispersed herd, 83·7 per cent. in the four-group herd, and 18 per cent. in the ten-group herd.

Thus, while *dispersion into* relatively large groups during the pre-epidemic phase had little influence on the spread of enteric infection among the mice at risk, dispersion into many small groups had a marked inhibitory action. Re-aggregation was followed by a further spread of infection among this herd, but on the 161st day after the experiment started they still showed a relatively low mortality from this disease. Before discussing the significance of these results, we may consider another experiment, in which dispersal was carried out at a later stage of the *epidemic process*.

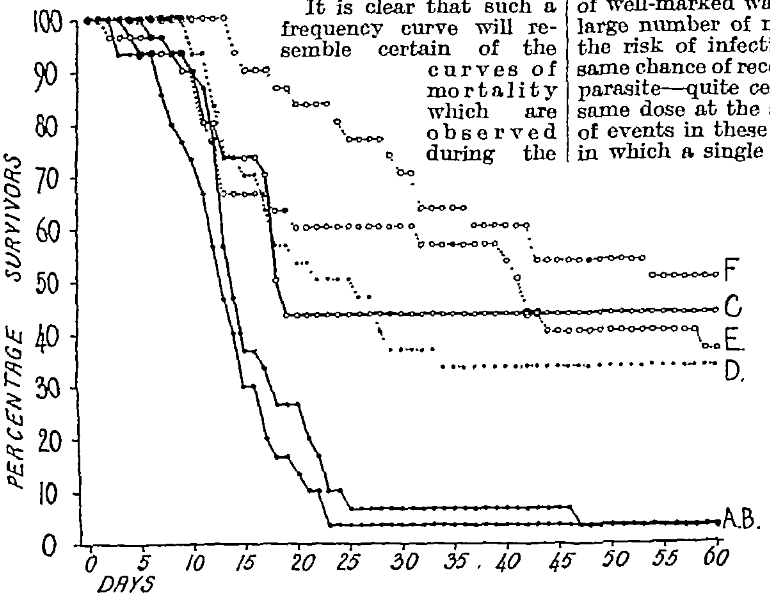
This epidemic, which is recorded in Chart 13, was initiated by adding 420 normal mice to 60 others, among which enteric infection was actively spreading. This mixed population was allowed to remain in a large cage for seven days, during which time 45 deaths from mouse-typhoid occurred among the 420 added mice, showing that an epidemic was well established. On the eighth day 360 survivors from the 420 mice were divided into four herds, each of 90 animals. Two of these, recorded in the chart as P 1 and C 1, were each kept as a large group in *a single* cage. The two others, referred to as P 2 and C 2, were each dispersed into 18 small groups, each of five mice. The *survivors from* each of these dispersed herds were re-aggregated in a single cage on the forty-second day, and the experiment was continued until the eighty-fourth day. The mice constituting the herds P 1 and P 2 were injected with a bacteriophage active *against B. aertrycke*, but this fact does not concern us here, and it will be seen from the chart that their fate did not differ from that of the mice of the control *herds* C 1 and C 2, which received no treatment. Confining our attention to the effect of dispersal and re-aggregation, it is clear that distribution into many *small groups during the epidemic* phase has no such marked effect as was observed when dispersal was carried out before any wave of mortality had *been developed. During the first three* weeks there is no significant difference between the course of events in the four herds. The undispersed herds suffered, during this period, mortalities of 72·2 and 67·8 per cent., and the two dispersed herds mortalities of 64·4 and 62·2 per cent. From this point onwards, however, the $l_x$ *curves* diverge. The two curves recording the proportion of survivors in the dispersed *herds show that change* in direction which we have already noted in describing other epidemics of mouse-typhoid, while the two curves *recording the fate* of the undispersed herds continue their downward *course for* some time longer. On the forty-second day, when the mice in the dispersed herds were re-aggregated, the percentage of survivors in these two *herds* amounted to 25·5 and 24·4 per cent., and in the two undispersed herds to 11·1 and 7·8 per cent. In this case the re-aggregation of the dispersed *herds* was not followed by any marked rise in the death-rate, though *a* few deaths occurred between the forty-second and eighty-fourth days. The percentages *of* survivors on the eighty-fourth day were 17·8 and 13·7 per cent. among the dispersed herds, and 8·9 and 2·2 per cent. among the undispersed herds. In all cases the mortality was almost entirely specific.

Considering these two experiments together, it appears that dispersal carried out during the earlier very few or none will die within a very short interval or will succumb after a certain limit of time. As Webster himself has shown, a curve essentially similar in form is obtained after inoculating mice with a poisonous metallic salt.

---

* *The first and second lectures* appeared in THE LANCET of March 6th and 13th respectively.

CHART 14.



It is clear that such a frequency curve will resemble certain of the curves of mortality which are observed during the course of an epidemic. Webster[27] has noted this resemblance between the curves obtained in his own inoculation experiments and some of those recorded by Amoss[21] in the experimental epidemics in which mice were added irregularly to an infected population. From this resemblance he has drawn the conclusion that the form of the mortality curves in the experimental epidemics depends upon the varying degree of susceptibility within a mouse population simultaneously exposed to a fixed dose of mouse-typhoid bacilli. We are not certain how much significance Webster attaches to this suggestion. If he implies that very occasionally, and under very exceptional circumstances, a large number of hosts may simultaneously receive the same dose of a virulent organism, and that, should such an event occur, the form of the distribution in time of the resulting deaths will be mainly determined by the variable resistance of the hosts, then we have no criticism to make. That Webster does set some limiting condition to the application of this hypothesis to natural or experimental epidemics is clear from several of his papers; but, unless we have misread him, he regards this variation in normal resistance as the factor which determines the time-distribution of deaths in any well-marked wave of mortality during an experimental epidemic of mouse-typhoid. In fact, he uses a term which we certainly cannot accept, in speaking of this frequency curve as "the simple epidemic curve."

It is not necessary to discuss this question in any detail. In the numerous experiments which we have described above, in which the daily addition of normal mice to an infected herd was associated with a series of well-marked waves of mortality, it is clear that no large number of normal mice, hitherto unexposed to the risk of infection, were suddenly exposed to the same chance of receiving any given dose of the bacterial parasite—quite certainly, they did not all receive the same dose at the same moment of time. The course of events in these experiments, and in many of those in which a single large batch of mice were added to infected companions, indicates clearly that the rise of a well-marked wave of mortality is preceded by a wide spread of infection, which will probably have modified in many ways the original condition of the animal hosts at risk.

The successful analysis of the epidemic process is, in our view, unlikely to resolve itself into any such simple formula. We should note that Webster himself favours a more complex hypothesis, in connexion with the spread of a pasteurellar infection among rabbits.

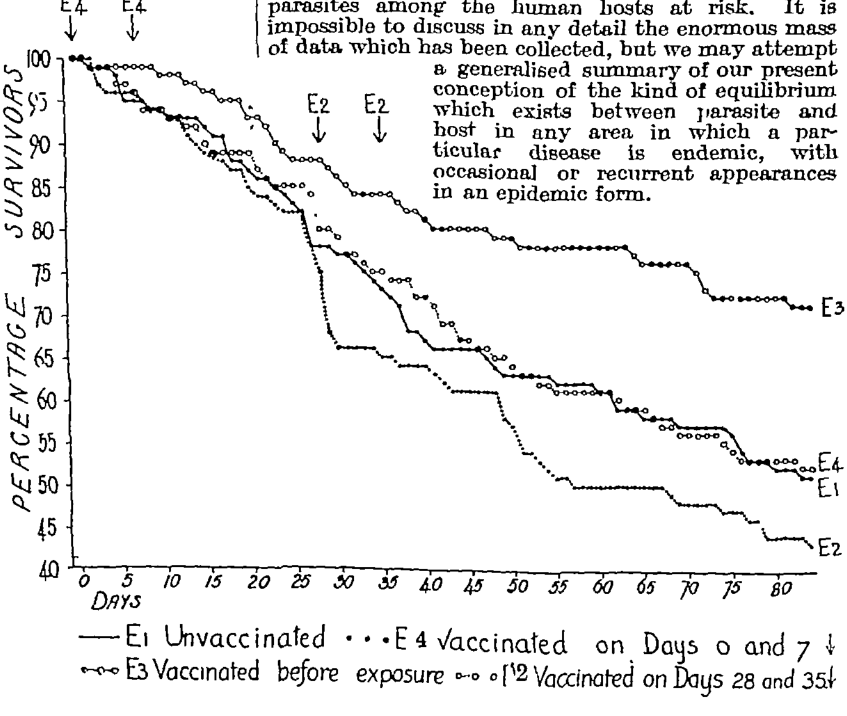
## EPIDEMIC SPREAD OF INFECTION: SOME GENERAL CONSIDERATIONS.

If we look beyond our experimental results, and include in our survey the bacteriological data which have been obtained in the observation of naturally occurring epidemics, can we, without too adventurous an application of the dangerous argument from analogy, obtain any further suggestions as to the nature of the epidemic process?

The results which have been obtained along two lines of inquiry appear to us to be particularly pertinent to the points at issue.

The first of these is that which has been developed in connexion with the so-called carrier problem, and which has led to a steady accumulation of knowledge concerning the distribution of certain bacterial parasites among the human hosts at risk. It is impossible to discuss in any detail the enormous mass of data which has been collected, but we may attempt a generalised summary of our present conception of the kind of equilibrium which exists between parasite and host in any area in which a particular disease is endemic, with occasional or recurrent appearances in an epidemic form.

CHART 15.



It has become clear that, where these conditions exist, the clinically recognisable cases of disease form only a fraction of the infected individuals of the host species. Adequate bacteriological examination will reveal numerous hosts who are suffering from some atypical disturbance of health, and from whose mucous surfaces or excreta the specific organism of the disease can be recovered, and others, still more numerous, who are harbouring the parasite without any definite evidence of illness. If we examine adequate samples of cases of disease, of contacts with atypical lesions or symptoms, of healthy contacts, and of healthy non-contacts, we shall generally find a descending order of frequency of the presence of the specific parasite; but in many cases—and this is a point of particular importance—we may obtain equal values for the carrier-rate in healthy contacts and non-contacts within an epidemic area, so that there is no reason to suppose that contact with a clinically recognisable case of disease is the main mode of infection leading to the carrier state.

The practical significance of this distribution of different states of equilibrium between the individual hosts and the parasites they harbour will, of course, depend on the relative frequency of the various classes, and it is here that more knowledge is urgently required. In some infections, such as cerebro-spinal fever, we know that the cases of disease are in an insignificant minority, that they are, to use a convenient but equivocal term, an epiphenomenon. In this case the carrier-rate among the population at risk may be carefully observed as it rises from a figure of a few units per cent. to 20 per cent. or more, before a single case of meningitis occurs, and the actual outbreak of disease may number only a few cases among many thousands at risk. The real epidemic, as Arkwright has pointed out, is an epidemic prevalence of meningococci in the naso-pharynges of the population at risk. No purely clinical description of the course of events could ever have been other than a revelation so partial as to obscure all essential truth.

We can be fairly sure that poliomyelitis and encephalitis lethargica behave much like cerebro-spinal fever in this respect, because the bacteriological findings in the latter disease have taught us how to interpret the clinical observations in the two former. In the case of poliomyelitis, indeed, the carrier state has been shown to exist. It is probable that diphtheria, and perhaps scarlet fever, show a higher ratio of cases to carriers, though this ratio is certainly much less than unity. It is possible that such a disease as small-pox is at the other end of the scale, and that here the carriers are in an insignificant minority, though none will deny the frequency of the atypical case. I would hazard the personal guess—it is nothing more, and I have found few supporters among those best qualified to offer a clinical opinion—that this relation only obtains in an area in which small-pox is introduced after a considerable period of complete freedom from this disease, and that when we are faced with an annually increasing prevalence, as we now are in this country, we may feel fairly confident that the carrier is there, although he receives no professional recognition. It would appear that the more we have learned of the bacteriology of any particular infective disease, the more probable is it that the distribution of the parasite is far wider than the distribution of the disease.

The second line of inquiry has been more recently developed, but has already yielded evidence of the greatest significance. The introduction of the Schick test has enabled us, in the case of diphtheria, to add to our study of the distribution of the parasite a study of the distribution of resistance among the hosts at risk. Further, and even more significant than this, we can now observe the gradual immunisation of an infected herd, and correlate the spread of immunity with the spread of the parasite. Such a study as that which Dudley[24] has carried out, on the natural immunisation of the inmates of an institution during the progress of an epidemic of diphtheria, affords an admirable example of the most fruitful kind of field observation based on bacteriological data.

So far as we are justified in combining our experimental data with such field observations as those we have referred to, it would seem that we may regard the epidemic spread of any disease as involving a series of reactions between parasites and hosts which tend to produce quite different results. We may suppose that the primary interaction of the pathogenic bacteria and the susceptible hosts will lead to fatal infections, to infections clinically recognisable as cases of disease, to atypical infections involving some recognisable departure from health, and to latent infection or to the carrier state, in which the host may harbour the parasite over long intervals of time without any sign of disease. The proportions which these various products of reaction bear to one another will be determined by various factors, the isolation and measurement of which is the main object of our experimental inquiry.

We may suppose, by an induction the imperfection of which we fully realise, that those hosts who contract a non-fatal infection will thereafter possess an altered resistance to the specific parasite, and that this alteration will, in general, be in the direction of an increased resistance of varying duration. Using a chemical analogy of doubtful validity, we may regard the reaction as in some degree autocatalytic, since some of the products of the primary reaction will, by their mere presence, tend to accelerate the shift of equilibrium in the direction of the accumulation of infected hosts. But one line of reaction will produce a somewhat different result. If a non-fatal infection leads to immunisation, there may be a gradual accumulation of resistant individuals who may be relatively unresponsive to further doses of the bacterial parasite, and a consequent elimination of those susceptible hosts who form an essential reagent. It would be easy on these grounds to account for the predominant importance of a steady immigration of susceptibles, which has emerged so clearly from our experimental studies.

If such a working hypothesis should be established on a firmer basis by further research, it would appear probable that the relative amounts of those products of an epidemic, which are clinically recognisable as disease or death, will depend upon the relative rate of those reactions which lead to immunisation on the one hand and to disease on the other. If the conditions favour immunisation there may be a widespread epidemic with few cases and still fewer deaths; if they favour more severe infections there may be more disease, and many of the cases may end fatally. If we could determine the nature of the factors which control the rate of these various reactions, we might reasonably hope to interfere successfully in the epidemic spread of disease, by breaking some essential link in the sequence of events on which this spread depends.

## PRACTICAL APPLICATION OF PRESENT KNOWLEDGE.

It seems desirable to make some attempt to consider the efficacy of our present methods of dealing with infective disease, and of possible developments of them, in the light of the knowledge which has so far been acquired. Such consideration is more than a little premature, and I would offer it in the spirit of a famous contributor to the theory of the ills of populations, who says:—

> "By pursuing this plan, however, I am aware that I have opened a door to many objections, and, probably, to much severity of criticism; but I console myself with the reflection that even the errors into which I have fallen, by affording a handle to argument, and an additional excitement to examination, may be subservient to the important end, of bringing a subject so nearly connected with the happiness of society into more general notice."

It is natural first to consider those administrative measures which may be employed to lessen the chances of contact between infected and susceptible hosts, and we may divide such measures into those which are specific, in the sense of dealing with particular diseases, and those which merely aim at a general reduction in opportunities for the transmission of infection.

Under the first heading we must obviously consider the probable efficacy of the isolation of cases of infective disease. The experimental and bacteriological data at our disposal do not suggest that this method has much to recommend it as a measure designed to reduce the frequency of disease and death, due to an infection which is endemic among the population at risk. Without pressing the analogy, we might suggest that such a procedure is rather like the continuous removal of an unpleasant product of a chemical reaction, in the hope that the reaction will thereby be brought to an end. A more hopeful procedure would be to determine the conditions of the reaction, as a preliminary to altering them. The opinion of experienced administrators, on the actual results of the policy of isolation, bears out the expectation based on conclusions from bacteriological observation and from experiment.

The isolation hospital may, perhaps, be defended on the grounds of the benefits which it confers on the sick persons for whose treatment it provides. As a means of lessening the general incidence of infective disease it receives little support on scientific grounds, and apparently finds few friends among those who are best fitted to judge of its practical effects. It is, of course, reasonable to argue that the isolation of a person sick of an infectious disease must of necessity reduce the risk run by a few persons who would otherwise be brought into contact with the patient. This none can deny. The point at issue is whether the spread of infection from diagnosed cases to susceptible hosts forms such a significant fraction of the total spread of infection, which is occurring in the affected area, that the suppression of this one avenue of spread will appreciably lower the incidence of disease.

One point may be here stressed. It seems to us to be no sufficient answer to a criticism of any particular administrative method to suggest that it probably does *some* good, and that while any doubt remains the public are entitled to such protection as the enforcement of that particular measure may possibly afford. The hard facts of the case are that public health administration is expensive in effort, time, and money, and that the total expenditure which can be devoted to the prevention of disease is limited by the available resources. Elementary economy demands that we should apply our efforts in those directions in which we can hope for the best return.

If the isolation of the sick offers little hope of the effective control of infectious disease, can we expect better results from the detection and isolation of carriers? The answer here must be given by experience. In certain diseases, and in small outbreaks in which the entire population at risk is susceptible to unusually complete control, as, for example, in outbreaks of diphtheria in institutions, much may be done in this way. In a few diseases, such as typhoid fever, in which the total incidence may be relatively small, and in which a few chronic carriers may be the only important sources of infection in a large district, the detection and control of these individuals is obviously indicated. In most diseases, and in all cases in which we are concerned with an endemic infection widely distributed among a large uncontrolled population, the detection and isolation of carriers has been shown to be impracticable.

Turning to those administrative measures which bring about a general reduction in the opportunities for the transference of infection from host to host, theoretical considerations suggest, and practical experience affirms, that any measure of this kind is to be welcomed with enthusiasm. Any improvement in sanitation, which ensures a clean water, or milk, or food supply, which reduces the frequency of insect vectors of infection, or which reduces close contact between individuals, may be expected to lead to a reduction in the incidence of those diseases, with the transference of which that particular measure of sanitation interferes. This expectation has been fulfilled whenever an effective measure of reducing the general opportunities for the transference of a particular infection has been established.

This brings us directly to the vexed question of overcrowding. The dominating influence of this factor on the incidence of human and animal disease has been established beyond question. Perhaps one of the most convincing examples of its influence has been provided by the studies which were carried out during the late war on the incidence of cerebro-spinal fever, particularly the observations made by Glover.[67]

It seems possible, however, that we may expect too much in future from improvements along these lines, though they should clearly be exploited to the limits of their possibilities. I would suggest that it might be helpful to adopt a bacteriological definition of effective overcrowding as " any spatial distribution of a population which favours the frequent transference of a particular pathogenic parasite from host to host." On this definition overcrowding, as it is concerned in the spread of infection in typhoid, influenza, malaria, or typhus, would depend on entirely different factors. I think that the absence of some such definition has led to a little confusion in certain statistical inquiries. Some measure of overcrowding must be adopted in calculating its probable influence on the spread of any given disease, and it is usual for the statistician to employ some such measure as the number of houses per acre, the number of families per house, or the number of persons per room. I would suggest that such a measure may entirely neglect the effective overcrowding to which a population is subjected. At the moment, the enemy which threatens us is respiratory disease. Influenza and its allies determine the reigning epidemic constitution. It seems very possible that it is our trains, and tubes, and 'buses, and trams which ensure a highly successful admixture of hosts and ample opportunities for transference of parasites. The more we expand our residential suburbs, keeping our workshops in a few large centres of industry, the more shall we accentuate this particular difficulty. In dealing with the acute respiratory diseases of mankind it does not look as though the reduction of effective overcrowding were likely to prove the strong suit in our hand. We are faced with another illustration of the wisdom of Robert Watt's aphorism : " We may, it seems, under permission of Divine Providence, deprive death of some of his apparently most efficient means; but deprived of these, new means are discovered, or the old improved."

In the control of epidemics among animals we are not limited by the considerations of social expediency, and more may be hoped for from a strict control over the movements of healthy and infected stock. It is probable, however, that the principles which limit the utility of such methods are as applicable to animal as to human diseases. We would express a personal doubt as to the benefit which is likely to result from the policy of slaughtering cattle which form part of a herd, among which a case of foot-and-mouth disease has been diagnosed. In a country which had been free from this infection over a long period of time, such a policy might well be adopted in an attempt to stamp out the new infection before it obtained a foothold. But, once that foothold has been obtained and recurrent outbreaks have shown that the infection has become widely generalised, it seems possible that slaughter may have effects somewhat different from those intended. We have seen that the continuous immigration of susceptibles appears to be the most important single factor in maintaining the level of epidemic prevalence of an infective disease. If we may assume that slaughter has, in fact, failed completely to stamp out infection—and the history of the past few years suggests that this is the case—then it would seem that the elimination of all those animals which have been exposed to risk, and their replacement by uninfected susceptibles from other areas, may have little to recommend it as a means of reducing the incidence of the disease. In the old days of sailing ships and press-gang, the experienced captain held strong views on the unwisdom of introducing among his crew any large number of men, however healthy, who were " not salted to the ship," for he knew from bitter experience that the mingling of samples of humanity who had for long been exposed to different risks of infection might have disastrous consequences. The principle is probably of wide application in human and animal disease.

It would seem that our best hope of controlling those infectious diseases, which refuse to yield to those means of general sanitation which are compatible with the modern organisation of our social life, lies in devising some effective means of immunisation, and so raising the average level of herd-resistance. We have already referred to the use which has been made of the Schick test in the study of diphtheria. The results which have been obtained by active immunisation based on the information obtained by the use of this test afford an excellent example of the success which attends the application of scientific methods to the prevention of disease. No better instance of the utilisation of such methods could be cited than is to be found in a recent paper [illegible] by Okell, Eagleton, and O'Brien.

We have seen reason to believe that the efficacy of such methods may vary greatly according to the period of the epidemic process at which they are applied. If the best method of immunisation at our disposal will yield only a slight increase in the average herd-resistance, it may make all the difference whether such immunisation be applied early or late in the spread of infection. We cannot envisage with equanimity the immunisation of the whole of mankind to all the infectious ills which flesh is heir to. If, as seems very probable, any outbreak of infectious disease is preceded by a redistribution of the specific parasite among the population at risk, a knowledge of such a redistribution might yield valuable indications as to the appropriate measures to be adopted. It is possible that one of the duties of the public health intelligence service of the future will be to keep a watchful eye on variations in the microbial flora of mankind, by a continuous sampling of the population. Under the auspices of the Ministry of Health we are carrying out such a sampling of the Manchester population with regard to some of the more important members of the nasopharyngeal flora, and correlating the results with the incidence of the various types of respiratory disease.

It seems probable, however, that the earliest testing, on a field scale, of any principles which may be derived from experimental results must be carried out in connexion with animal rather than with human infections, since the opportunities for control and for the collection of special data are so much greater; and I would end as I began by emphasising the need for still closer coöperation between the students of human and of animal disease, and for a broad biological outlook on the part of both.

I should wish, on behalf of Dr. Greenwood and myself, to express our thanks to those who have helped us during the course of this work; on the bacteriological side to Dr. G. S. Wilson, Mrs. Joyce Wilson, Dr. L. P. Lockhart, and Miss E. R. Lewis; on the statistical side to Miss E. M. Newbold, Miss Thomas, and Messrs. Fanning and Martin; and to Mr. W. Bale for his continuous assistance in the care of our stock of normal and infected mice.

We acknowledge our great indebtedness to the Medical Research Council for their generous support throughout the past five years. Investigations of this nature are necessarily protracted and expensive, and without the Council's support they could not have been undertaken.

*Bibliography.*—The bibliography to Lectures I., II., and III. appeared in THE LANCET of March 6th, p. 484.

---

DEATH OF SALFORD CORONER.—The death occurred at his home at Altrincham, near Manchester, on March 8th, of Mr. Arthur Holmes, coroner for the borough of Salford. Mr. Holmes was in his sixty-eighth year and was a son of the manse; he was appointed coroner in 1896 on the death of Mr. Frederick Price. For many years it was the custom in the borough to hold inquests on licensed premises, and during a long murder case a missing witness was found to have been taken into custody, as he had been drinking to excess during the long wait. This untoward incident was largely responsible for a room being set apart in Pendleton town hall for sittings of the coroner's court. It was in this court that the arsenic in beer scare was first brought to light and investigated. For some time Mr. Holmes acted as clerk to the Manchester Port Sanitary Authority.

# DIABETES MELLITUS:
## A RECOVERABLE DISEASE?

BY G. H. PERCIVAL, M.B. EDIN.,
D.P.H. EDIN. & GLASG.

*(From the Department of Therapeutics, University of Edinburgh.)*

THE following cases, selected from records of a large number of diabetics who have been treated in the Royal Infirmary, Edinburgh, are reported to illustrate the possibilities of modern treatment.

The diet scale used is that described by Prof. Murray Lyon,[1] consisting of three types graded according to the carbohydrate-fatty acid ratio—viz., the A diet having a ratio of 2 to 1 or over, the B diet having a 1 to 1 ratio, and the C, in which the ratio approaches in the lower caloric values, and reaches in the higher, the optimum ratio of 1 to 1·5. A further modification is found in the D diets, where the ratio remains 1 to 1·5, but in which the protein content is increased. The A diets are always accompanied by insulin, and are employed to abolish severe clinical ketosis; the B diets *may* be used with or without insulin to get rid of glycosuria; the C diets are used alone to estimate the patient's tolerance, and also with or without insulin to slowly advance the caloric intake. Patients may be finally kept on the higher values of C or changed over to the D scale, which affords a more suitable maintenance diet on account of its higher protein content. The various diets are selected and interchanged to suit the requirements of individual cases during varying degrees of tolerance. They are referred to under the group letter, followed by a figure indicating the number of available calories in hundreds—e.g., a B 15 diet is one yielding 1500 calories, built to give a carbohydrate ratio of 1 to 1.

Insulin is withheld, except in cases possessing such a low carbohydrate tolerance that it is impossible to abolish glycosuria, or to continue an adequate caloric intake, by dietary measures alone. When required, it is injected two hours before a meal, except in very severe cases, when the interval is reduced at first to one or one and a half hours. All patients requiring insulin are taught, and those who have had preliminary hospital supervision have in most cases experienced, the symptoms of hypoglycæmia, and their remedy. The urine is tested for sugar daily by Fehling's method by the patients themselves, and also once weekly by the sister dietitian.

### *Group A.*

CASE 1.—A male, aged 23 years, had complained of lack of energy and tiredness on rising in the morning for about two months. This was attributed to frequent coincident attacks of trigeminal neuralgia, and two carious teeth were removed and a root abscess drained. About this time he commenced to be troubled with increasing frequency of micturition accompanied by urgency, and occurring especially after meals. The lassitude and urinary symptoms continued for three weeks. His urine contained 2·5 per cent. glucose one hour after a meal (estimated by Benedict's method), and a trace of acetone was present. The fasting blood-sugar content was 210 mg. per cent., and a sample of urine taken at the same time contained 0·5 per cent. glucose. At that time his weight was 9 st. 12 lb., height 5 ft. 7 in. He was given a B 15 diet and in two days the urine was sugar-free. This diet was continued for a week, then he was given C 13, with an increase of 100 calories every third day till C 28 was reached. He was kept at this level for a week, then changed to the D scale and raised to D 30. During this period of dieting he lost 9 lb. weight *during the first fortnight*, but this was soon regained. Lassitude, neuralgia, and urinary symptoms quickly disappeared during the first month. Eight months have elapsed since he first came under observation, and he now takes an ordinary diet with some limitation of cereals, and avoids substances containing actual sugar. Glycosuria occurred on one occasion after a full ordinary meal had been taken, as the patient felt sure that he must have completely recovered. The experiment was not repeated, and there has been no reappearance of glycosuria.

Seven similar cases have been examined, and a general summary will avoid much repetition.

Four of the cases were males and three were females, the ages ranging from 24 to 10 years. They sought advice for some of the following symptoms: Tiredness, frequent and urgent micturition—worst after meals and accompanied by polyuria; neuralgic pains; thirst, and in some cases hunger; itching of the skin; and in one case, which has previously been fully reported,[1] xanthomata of wide distribution were present. The duration of these symptoms varied from one to three months, during which time they had increased in severity. On examination glucose was found to be present in the urine, in some instances accompanied by acetone. When treatment was begun the initial diet varied from 900 to 1500 calories on the B scale, and the urine was rendered sugar-free in from three days to a week. Thereafter the diet was raised quickly to about a 2500 caloric value on the C scale, and later slowly increased to 3000 or 3300 calories on the D scale. One female remained at C 25, the tolerance being limited to this level, and this amount was sufficient for her body requirements. The increase to the highest values was made over periods of from one to six months. In two cases small amounts of sugar were again found in the urine after two and four months respectively on D 33. The diet was accordingly reduced to C 15 until the glycosuria was rectified, then a daily increase of 100 calories was allowed till the previous high level had been attained. Five of the patients, including the two slight relapses, have remained sugar-free for periods varying from seven months to four years and are now taking practically a normal diet, with limitation of bread and cereals, and omission of actual sugar. In three cases slight acetonuria was present on several occasions, but vanished when the fat intake was reduced. These patients were instructed on the necessity of regulating the distribution of fats so that they should always be taken along with an adequate amount of carbohydrate.

### *Group B.*

CASE 1.—A previously healthy school-boy, aged 16 years, had complained for one month of being easily fatigued, of rapid loss of weight, of frequent and urgent micturition, and of thirst. Latterly he felt constantly languid and drowsy. The urine was loaded with sugar and acetone. He was admitted to hospital, and during the 15 hours following admission passed 70 oz. of urine. He was markedly emaciated, was 5 ft. 11 in. in height, and weighed 8 st. 13 lb. The skin was dry and rough, the tongue dry and raw, the teeth were in good condition, and the lungs showed no evidence of tuberculosis. He was put on a B 15 diet with 30 units of insulin divided into three doses of 10 units each. On the first day of treatment his urine contained 30·24 g. sugar out of the 124 g. in the diet, but after continuing for five days the urine was sugar- and acetone-free and the thirst and polyuria had disappeared. The diet was changed to C 10 and increased daily by 100 calories till a daily intake of 165 g. carbohydrate in a 2800 caloric diet was being given. During this rapid increase there was no return of glycosuria or ketonuria, and on account of slight hypoglycæmic symptoms after the first injection of insulin on four successive mornings the drug had been reduced to a daily dose of 15 units. The patient was discharged on a C 28 diet with 15 units of insulin after 10 days in hospital. Three weeks after discharge he was able to stop insulin altogether, having gradually reduced the daily dose during this period. During the ensuing four months his urine has remained sugar- and acetone-free on a D 28, with an additional allowance of half an orange per day and a preparation of almost sugarless marmalade (1 per cent. available carbohydrate), and in spite of an attack of tonsillitis and a gastric upset of a few days' duration. He has put on 1 st. 6 lb. in weight, and the starving blood-sugar content is now 150 mg. per cent., and the blood-sugar curve of a normal character.

CASE 2.—A girl, aged 11 years, had complained of thirst, with parched mouth and lips, and polyuria, with urgent and frequent micturition for the previous three months. Her urine was examined during this period and was said to contain 5·6 per cent. glucose before a meal and 15·5 per cent. one hour after the meal. During the preceding two years she had suffered from whooping-cough, chicken-pox, and rubella. She was admitted to hospital, was found to be very emaciated, weighing 3 st. 12¾ lb., her height being 4 ft. 7 in. The skin was dry and rough, the tongue raw. The patient was put on a B diet of 1000 calories, which was the following day reduced to 700 calories. On both days the total carbohydrate in the diet was excreted in the urine together with acetone, which was much increased with the lower diet. The clinical manifestations of acetonæmia were judged to be severe enough to require an A diet, and she was given A 17 for two days along with 30 units of insulin. This caused disappearance of the ketonuria, but 10·7 g. of sugar were lost in the urine on both days. The injected insulin was sufficient to account for all the sugar metabolised, the patient evidently having no insulin of her own available. The carbohydrate intake was reduced by giving a B 12 diet and the glycosuria stopped. The diet was changed to the C series and gradually advanced, and in six weeks the patient was able to take a C 21 diet, while the insulin had been reduced to one injection of 5 units daily. At the end of this period the patient was discharged, and continued treatment; her weight was now 4 st. 13 lb., showing a gain of 1 st. Two and a half months later she was able to stop insulin, having recently had several slight attacks of hypoglycæmia, and has remained sugar-free for two months. On several occasions she has had slight ketonuria, and the fats in the diet have had to be slightly reduced below the 1–1·5 ratio, with the desired result. She now weighs 5 st. 6 lb., having gained 2 st. 6 lb. since the commencement of treatment.

CASE 3.—A man, aged 43 years, had complained of polyuria, thirst, loss of energy, and fatiguability during the ten years prior to examination, when the urine was found to contain glucose and acetone. On admission his weight was 9 st. 8¼ lb., and insulin was essentially required to restore the sugar-curve to normal limits. He was discharged, taking C 26 and 15 units of insulin daily. Three months after discharge the diet was C 27, insulin was no longer required, and his weight had steadily increased to 10 st. 11 lb. During the ensuing seven months no insulin has been required, he has remained sugar- and acetone-free in spite of several colds, and his weight is now 11 st. 4 lb., an increase of 1 st. 9 lb. since the commencement of treatment.

CASE 4.—A male, aged 61 years, had suffered from polyuria, thirst, and tiredness for the past nine years. He had to stop work on account of this four years ago. He had been under medical supervision during part of that time, and is reported to have had constant glycosuria. One year ago gangrene of the right big toe commenced and slowly spread to involve the whole foot. Patient was admitted to hospital, put on a B 15 diet along with 45 units of insulin daily for two days. This reduced the glycosuria to a trace and abolished ketonuria. Then a mid-thigh amputation was performed. The day after operation the urine was sugar-free. The diet was increased gradually, and the insulin reduced till it was stopped altogether. He has remained sugar- and acetone-free for two months on a C 24 diet, and the wound has healed satisfactorily; polyuria and thirst quickly disappeared after treatment had been commenced.

### *Group C.*

CASE 1.—Male, aged 18 years, had severe diabetes of short duration and was treated in hospital immediately he was observed. Insulin was required, and he was discharged taking C 28 with 10 units of insulin daily in one dose given in the morning. He continued under this treatment for one month, remaining sugar- and acetone-free. During the next three months insulin was successfully decreased, till it was stopped, the diet now being D 20. He was kept at this level for five months, then, coincident with the onset of acute nephritis, sugar reappeared in the urine. A daily dose of 10 units of insulin was again required, and the constitution of the diet was altered during the acute stage of the nephritis. During the three weeks after recovery from the nephritis the insulin was reduced to 8 units with a D 28 diet. From the commencement of treatment patient gained 2 st. in weight.

CASE 2.—Male, aged 32 years, treated in hospital for severe diabetes requiring insulin administration at first. Discharged after four weeks on D 28, without insulin, and weighing 8 st. 5 lb. He continued on this diet for seven months without glycosuria, then showed a trace for several days. The diet was reduced to 300 calories on the B scale and gradually increased to D 28. This got rid of the glycosuria, which remained absent for a further five months. The glycosuria then returned for no obvious reason and could not be abolished by dietary measures so as to permit a suitable maintenance diet, and during the ensuing six months his tolerance fluctuated and he required from 3 to 15 units of insulin daily on a C 24 diet. His weight is now 8 st. 9 lb., about 8 lb. below the standard for his age and height. All through the treatment he showed frequent traces of acetone during and in the absence of glycosuria.

### *Group D.*

Male, aged 38 years, had complained for some months of thirst, polyuria, failing eyesight, weakness and fatigue, and loss of weight. He was treated in hospital, required insulin, and was discharged on C 25 with 15 units daily. In four months the diet was raised to C 26, and the insulin reduced to nil, and he continued sugar-free on this dietary for one month. He then developed a persistent slight glycosuria, and a daily injection of 5 units was given. This was sufficient to clear the glycosuria, and after six weeks the insulin was stopped, following a fairly severe hypoglycæmia. For the next two months he remained sugar-free on a C 21 diet containing 106 g. glucose, in spite of a peritonsillar abscess, for which he was treated in hospital. He next developed a severe cold, the glycosuria returned, and he again had 5 units of insulin daily. This was stopped at the end of five weeks, and for two months the patient has been free of sugar on a C 24 diet. His weight throughout treatment has remained about 10 st. 10 lb.

Fourteen cases are divided into four groups: (a) Seven patients in whom the disease was of a mild character, who were treated by dietary measures alone, and who have now regained almost a normal tolerance. (*b*) Four patients who required insulin treatment when first observed, but who regained sufficient tolerance to enable them to discontinue its use, while continuing to take a generous maintenance diet. (*c*) Two patients, who, although like those in group B were able after a time to discontinue insulin, again required it, owing to a further decrease in pancreatic function. (*d*) One patient who twice needed insulin for short periods after having first ceased to require it, and following each "course" was able to take a sufficient diet.

### *Principles of Treatment.*

The severity of the symptoms, the presence of ketonuria, and the effect of large doses of insulin indicate that the common condition in all these cases was one of decreased activity of the insular tissue of the pancreas. The principle underlying treatment has been to permit physiological rest to this organ in accordance with Allen's findings in animal experiments. Wherever possible this has been attained by diet alone, insulin being added only where the diet was insufficient or where ketosis was present or threatened. When the condition has been improved for a time and then glycosuria returns (indicating over-taxation of the powers of assimilation) the pancreatic function is again immediately rested as completely as possible, and later the diet is very gradually increased.

### *Results.*

The beneficial effect of this line of treatment is forcibly illustrated by those cases in which large doses of insulin have been diminished and ultimately stopped, while the patient has continued to take a generous diet, the constitution of which presents no extreme variation from the normal.

It is reasonable to assume in cases showing genuine return of tolerance and an increasing capacity for naturally metabolising sugar that there is some return of functional efficiency of the pancreas, possibly a regeneration of islet tissue, and an increased natural production of insulin. The occasional reappearance of glycosuria may be explained as being due either to mild intercurrent infections, such as coryza, which are usually coincident and often precede, or to functional over-strain entailed by a too generous diet. It is worthy of note that when insulin was once more necessary in the treatment of these relapses the dose required was small. Further, the dose did not need to be progressively increased, but could be reduced, and in some cases finally discontinued. In some of the cases treated by diet alone a sugar tolerance approaching almost to normal has been reached, and the damage to the pancreas has been apparently either recovered from or compensated for. On the other hand, in those who required insulin, the tolerance regained is not nearly so great, but, especially in the younger cases in group B, a still further improvement is perhaps possible, and at least the present degree of recovery should, with reasonable care, be easily maintained. The patients have never been subjected to a special glucose tolerance test after the commencement of treatment. The information as regards improvement to be gained from such investigation is not thought of sufficient value to justify the accompanying strain on the carbohydrate mechanism, and the diet which can be tolerated with absence of glycosuria is a more natural, if less direct, indication of the patient's capabilities. The object in reporting these cases is that they seem to emphasise, firstly, the controllable character of the disease in the majority of cases treated on physiological lines with the whole-hearted coöperation of the patient, and secondly, that a surprisingly adequate carbohydrate tolerance may be recovered.

I am indebted to Prof. Murray Lyon for permission to observe his cases and for suggestions as to the selection of those recorded.

# CHANGES IN VENTRICULAR RATE ASSOCIATED WITH STOKES-ADAMS ATTACKS IN COMPLETE HEART-BLOCK.

BY C. E. K. HERAPATH, *M.C.*, M.D. LOND.,
ASSISTANT PHYSICIAN, BRISTOL ROYAL INFIRMARY.

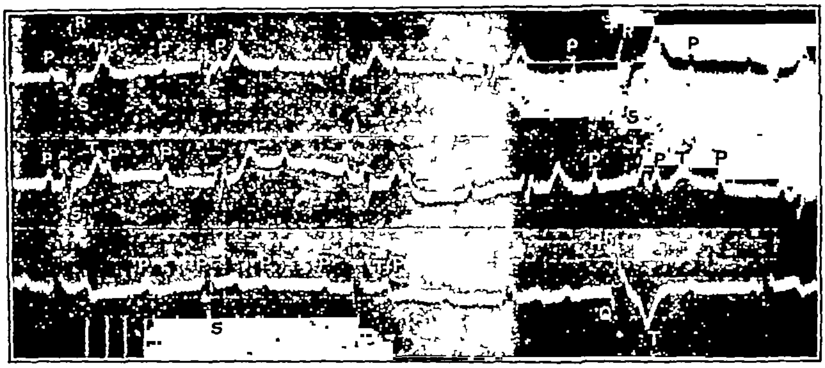
IT is well known that if the bundle of His be destroyed by a lesion, thereby cutting off impulses from the auricles to the ventricles, the ventricular action becomes slow and regular, and entirely different from that of the auricles. The ventricular contractions are then initiated from a rhythmic centre which lies in the bundle somewhere between the A.-V. node and the division of the bundle into its two branches. This idio-ventricular rhythm is usually between 30 and 40 beats a minute, but many variations are recorded. It may be as slow as 15 or as frequent as 60 per minute, and the regularity may be interrupted by premature ventricular contractions. Apart from these it is occasionally irregular, and sometimes it stops temporarily, giving rise to the Stokes-Adams syndrome, which is characterised by loss of consciousness and sometimes fits. The fits result from the longer ventricular pauses—that is, over 20 seconds—and are due to cerebral anæmia. The idio-ventricular rhythm is not under the control of the vagus, yet in some cases increase in rate is caused by emotion, exercise, and the injection of adrenalin. This suggests that it may be influenced to some extent by the sympathetic nervous system. It is my intention to review the literature on the subject, to give an account of a case showing Stokes-Adams attacks, and afterwards to discuss their causation.

In attempting to elucidate the cause of the ventricular arrest in these attacks the rate of beat before the attack and immediately afterwards is most important, but it is only in a few cases that this has been recorded, and there are few, if any, electrocardiograms which would be of the greatest assistance, inasmuch as they would reveal the type of the ventricular contractions. Quickening of the ventricular rate immediately before the attacks has been reported by Hay and Moore,[1] Ashton, Norris, and Lavenson,[2] Mackenzie,[3] and Cohn and Lewis[4]; in the last two the tachycardia has been attributed to runs of premature ventricular contractions. Slowing of the ventricular rate before the attacks has been described by Wardrop Griffith,[5] Barr,[6] Norfleet,[7] Phear and Parkinson,[8] and Cowan and Ritchie.[9] Attacks without previous alteration of rate are reported by Phear and Parkinson,[8] Barr,[6] and Erlanger.[10] The ventricular rate after the attacks also seems to vary; Wardrop Griffith[11] has described a rate of 100 per minute with premature ventricular contractions, Hume[12] describes a rate as fast and feeble, and Pepper and Austin[13] as rapid and running, dropping to 20 in two minutes. Byrom Bramwell[14] mentions two cases in which the rate after the attacks was 120 and 130 per minute, but suggests that the auricular rate had been counted instead of the ventricular. Scott,[15] Stengel,[16] Hay and Moore[1] and Jellinek and Cooper[17] record quickening at first but slowing down in a few minutes. Starling,[18] Barr,[6] Norfleet,[7] Jellinek and Cooper,[17] and Cohn and Lewis[4] record a slow rhythm after the attacks which gradually accelerates to the normal idio-ventricular rate. Wiltshire[19] reports a remarkable case in which 10 attacks are analysed; the rates of ventricular contraction before the attacks vary from 19 to 67 per minute, excluding the three final attacks, and he remarks that the length of the ventricular standstill showed some relation to the previous rate of the ventricles. When the ventricular rate had been slow the subsequent attack was likely to be short, but when the ventricle had been rapid the subsequent attack was likely to be long.

### *Clinical History.*

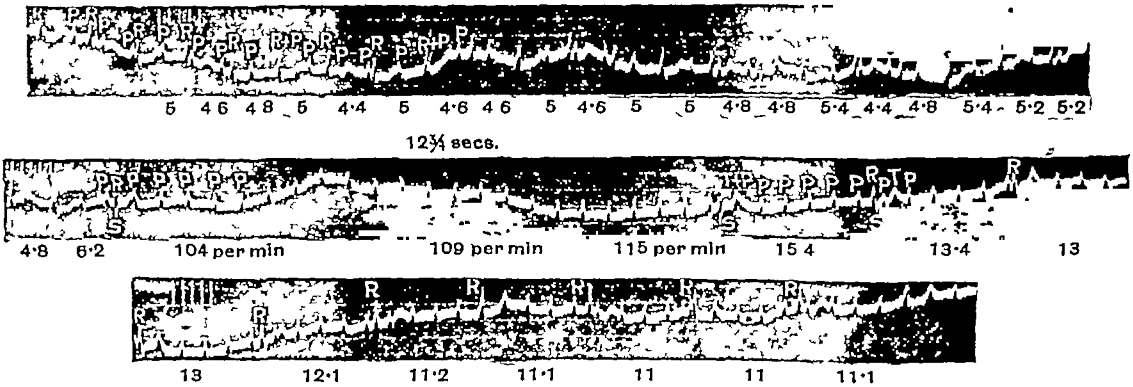
A man, aged 63, was sent to the out-patient department of the Bristol Royal Infirmary on April 9th, 1925, complaining of shortness of breath and weakness He had had a few attacks of what he called giddiness, and had fallen in some of these attacks. The heart was considerably enlarged and there was a systolic murmur at the apex. The blood pressure was 210 mm. Hg and the arteries were much sclerosed. The pulse was regular at 35 per minute. There was no history of syphilis, and the Wassermann reaction was negative. The electrocardiogram showed complete heart-block, the auricular rate being 100 and the ventricular 36 per minute. There was left ventricular preponderance with normal ventricular complexes, proving that the site of origin of the ventricular contractions was somewhere between the A.-V. node and the division of the bundle of His. There were a few premature ventricular contractions, of which the complexes were almost the opposite of the predominating complexes (Fig 1). On April 21st he developed frequent attacks of temporary loss of consciousness and was seen by Dr. Carey Coombs, who very kindly sent him to me at the Royal Infirmary. At the time of his admission he was having Stokes-Adams attacks at the rate of one every ten minutes or so. Clinically the attacks were all exactly similar in character; the pulse would suddenly quicken from 30 to about 60 per minute; this would continue for about 40 seconds and then the ventricles would stop and remain quiescent for from 12 to 15 seconds During this period he became slightly cyanosed and finally unconscious, with rather spluttering respirations. There was no convulsion. The radial pulse then returned, and he flushed and gradually resumed his normal florid colour. The pulse started slowly, and gradually quickened to about 35 per minute, at which rate it continued till the next period of tachycardia. He had no distress, nor was he frightened by the attacks, which he described as just falling asleep.

FIG. 1.



April 6th, 1925. Shows complete heart block. Auricular rate, 100; ventricular rate, 38 7 per min. Premature contractions in lead I., II., and III. marked +

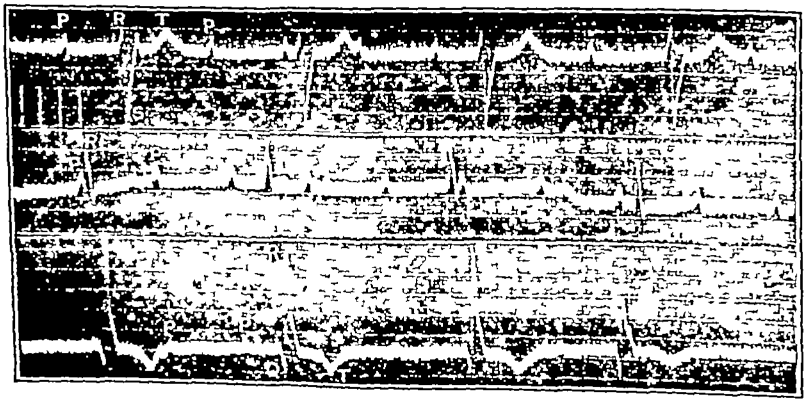
FIG. 2.



April 22nd, 1925. A continuous tracing of lead II. The intersystolic intervals are marked in fifths of a second. The time ordinates hardly show, but a few are etched in white.

These attacks were observed for about half an hour, and then he was removed to the electrocardiographic department, during which journey he had two more attacks. A tracing of two complete attacks was obtained and then, while still connected to the machine, he was given an intramuscular injection of 5 minims of adrenalin solution (1 in 1000)—the method of treatment described by Phear and Parkinson. At the time of injection the ventricular rate had quickened prior to another attack, and in due course this appeared. He had one slight attack after returning to the ward, and then no more till 7 the next morning, when he is said to have had two slight ones; a further injection of 5 minims was given, and he has had no more attacks up to the present time. Fig 2 shows a complete attack, lead II. being used. The tracing is a continuous one which has been divided into three portions.

FIG. 3.



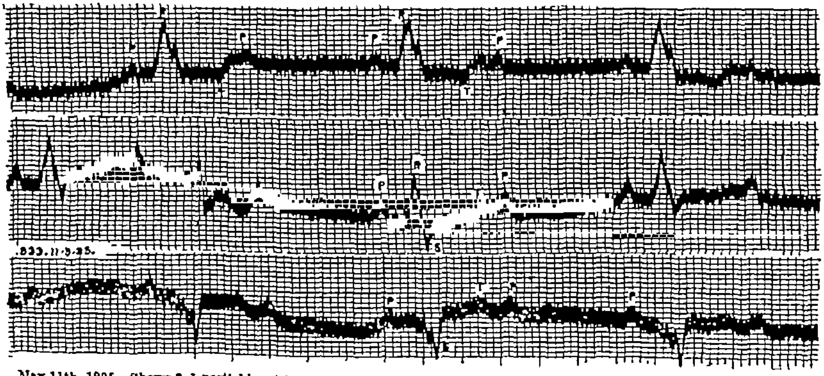
April 27th, 1925. Auricular rate, 85; ventricular rate, 35 per min A slow rhythm with the same complexes as the premature beats in Fig 1

### *The Electrocardiograms.*

The chief features are these: First, there is a rapid rhythm which varies from 62 to 63 per minute in rate. The rhythm is not perfectly regular, beats varying from 4·6 to 5·4 fifths of a second, but, allowing for distortion of some of the ventricular complexes from a superimposed P-wave, they are all of the same type, and similar to the complex of the premature beat seen in lead II. of Fig. 1, but the last ventricular complex before the ventricular stop is different; it is late, being 6·2 fifths of a second after the previous beat, and the complex is the same as the normal one in Fig. 1; there is a small R; a deep S and T is more pronounced. During the whole period of tachycardia the dissociation of auricular and ventricular rhythms continues, so that the block is still complete. The ventricles then stop beating but the auricles continue to beat regularly, though the rate has quickened to 104 per minute. During the ventricular standstill it quickens still further to 115 per minute. In the tracing obtained of each attack there is a lifting of the tracing at the eighth auricular wave following the ventricular standstill, representing probably the point at which consciousness was lost. The ventricles started again after a pause of 12½ seconds, beginning slowly and gradually quickening. It can be seen in the tracing that the first ventricular complex is of the same type as the last before the attack, the next four are more like those of the quick period except that they are wider, the Q.R.S. interval being 0·10 seconds, and in addition the R and S are thickened. After these four beats the remainder are identical with those of the tachycardia, and this rhythm continues for some time. The tracing obtained of the next attack was identical to this one with two exceptions: (1) The last beat of the ventricles before the stop did not differ from the previous ones, nor was there a longer inter-systolic period before it; (2) the ventricular stop was a little longer, lasting for 15 seconds, but there was no convulsion. After both attacks, when the rhythm had settled down, the ventricular complexes were of the original type of Fig. 1, though the change was not caught in the tracing. After adrenalin the original type of complex remained for as long as the tracing continued, which was for 20 minutes.

The next tracing was taken on April 27th (Fig. 3), and a regular slow rhythm was found, the rate being between 34 and 35 per minute. The ventricular complexes were found to be all of the type of those of the premature beats in Fig. 1. This rhythm continued, as seen in tracings not published, till May 4th. On May 11th an increase of rate to 18·2 was observed, and a tracing (Fig. 4) showed that the complete block had given way to 2–1 partial heart-block. This continued till May 14th, when he left the hospital to become an out-patient. He was next seen on June 22nd, when complete heart-block had returned (Fig. 5), the rhythm consisting of coupled beats with varying ventricular complexes, and the same rhythm was seen on his last examination on July 7th. It is noteworthy that complexes of the original type have not been seen since April 22nd.

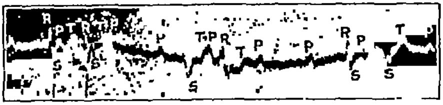
FIG. 4.



May 11th, 1925. Shows 2–1 partial heart-block. The ventricular complexes are very wide, suggesting deficient conduction down the right branch of the bundle. The ventricles are beating at the dictation of the auricles.

The only other electrocardiogram of an attack that I can find in the literature is that published by Gager and Pardee,[10] who show a tracing where, in complete heart-block, the ventricular rate quickened to 60 per minute immediately before a ventricular standstill. The ventricular complexes were at first of an abnormal type, being wider than normal, but during the tachycardia they gradually changed, becoming narrower and of the same type seen in other tracings of the case. They suggest that there was a shifting of the ventricular pacemaker from an abnormal situation to the normal during the tachycardia. Before stopping the last two ventricular beats become spaced out to 1·11 and 1·16 seconds. There is no explanation as to why the ventricular rhythm suddenly stopped. Unfortunately, the ventricular standstill was long enough to produce a convulsion, and therefore the resumption of the ventricular contractions could not be shown.

FIG. 5.



June 22nd, 1925. A short strip of lead II. showing a change in dominant rhythm and coupled beats, the second of each group being a ventricular premature contraction. The dominant ventricular rhythm shows another variation in ventricular complex.

### *Discussion.*

Much inquiry has taken place in the past as to the cause of the peculiar attacks of unconsciousness which may be found in cases of extreme bradycardia, and it is only about 25 years ago that it was recognised that they were connected with lesions in the bundle of His. Even now little is known as to the reason why the ventricle should stop so suddenly and then resume its activity. Erlanger[11] has shown experimentally that asystole of the ventricles may be expected in complete heart-block if there be a sudden cessation of a rapid stimulation of the ventricles. Hay,[12] in discussing this subject, expresses the opinion that in complete heart-block there is one point which produces the stimuli for ventricular contraction, and that any factor which could disturb this rhythm would cause ventricular standstill until such time as some other part of the muscle develops an inherent rhythm, or until the original point recovers its rhythmicity. Willius[13] points out that attacks of this kind may be expected more often in cases where the ventricular rate is in the twenties than when in the thirties, and in the thirties than in the forties. In electrocardiograms one can estimate the position of the point which produces the stimulus for ventricular contraction to some extent by the shape of the ventricular complex, and any changes which occur in the position of this point are demonstrated by a variation in the ventricular complex. We also know that it takes time for a new site for stimulus production to be developed in the bundle.

Returning to the case described, the following are the facts. An electrocardiogram of complete heart-block is shown, in which the ventricular complexes prove that the stimulus-production lies in the A.-V. bundle, for the complexes are of the normal supraventricular type. This rhythm is disturbed at times by premature ventricular contractions, the complexes of which are of the type of those arising from some portion of the right branch of the A.-V. bundle. Later we see that ventricular contractions showing this complex form a slow and regular rhythm. Between the dates of these two rhythms there occur attacks of tachycardia leading to periods of ventricular asystole, and *the ventricular complexes of this quick rhythm are in lead II. identical with those of the premature contractions* (Fig. 1) *and of those of the second rhythm* (Fig. 3). The complete heart-block gives way later to a 2–1 partial heart-block, and the ventricular complexes of this rhythm show that there is deficient conduction in the right branch of the A.-V. bundle (Fig. 4).

The deductions which may be drawn from these facts are as follows. In this case of complete heart-block with a normal supraventricular rhythm an irritable focus develops in the right branch of the A.-V. bundle; in the early stages this produces occasional premature ventricular contractions, a little later this irritability increases and the focus produces a simple ventricular tachycardia which displaces the original rhythm. This tachycardia exhausts the rhythmicity of this newly formed pacemaker and ventricular asystole occurs. After a rest the old site of stimulus production tries to resume activity (see the first contraction after the asystole in Fig. 2), but is again disturbed by the new rhythm, which slowly begins a rhythm of its own. After some time the old rhythm does manage to resume its activity, but it is soon overwhelmed by another attack of tachycardia from the new site of stimulus-production, and so on. An injection of adrenalin is given, and this so stimulates the cells of the bundle that the old rhythm is once more made powerful enough to take control. In a few days this rhythm disappears and the new site of stimulus-production permanently establishes its claim to be the ventricular pacemaker. No ventricular standstill occurs when this change is made, because the new rhythm is now capable of starting as promptly as necessary. There is nothing new in this explanation, but there is proof in the electrocardiographic tracings, and when more of these cases have been analysed by this means an explanation of all the varying attacks of ventricular asystole may be found.

### *Summary.*

A continuous electrocardiogram of the whole of a Stokes-Adams attack is reproduced. It suggests an explanation of the attacks of ventricular asystole in this case which is put forward in the text. The attacks of asystole in a case of complete heart-block were abolished by an injection of adrenalin, confirming the results obtained by Phear and Parkinson.

# Clinical and Laboratory Notes.

## DOUBLE INGUINAL HERNIA IN INFANCY: A NEW INCISION.

By JOHN T. MORRISON, O.B.E., F.R.C.S. Eng.,
HON. ASSISTANT SURGEON, ROYAL LIVERPOOL CHILDREN'S HOSPITAL AND LIVERPOOL STANLEY HOSPITAL.

IT often happens in operating on infants with a double inguinal hernia that the question arises as to the advisability of prolonging the operation by doing both sides at once. The general condition of the child, or difficulty with the administration of the anæsthetic, or both, may give rise to anxiety, and anything which will materially diminish the time taken by the operation will enable one, in certain cases, to avoid the necessity for a second surgical intervention. In dealing with the second side the time-consuming actions are (1) the changing over of the theatre staff and equipment to the other side of the table, (2) the rearrangement of towels and fresh preparation of skin, (3) the making and the closing of a second skin incision. These may all be avoided if the incision herein described is employed.

By means of a one and a half inch transverse incision along the line of the crest of the pubis efficient access may be obtained to either external abdominal ring. The incision is deepened till the surface of the aponeurosis is reached. A small double hook retractor is placed in the angle of the wound, and with quite moderate traction the region of the abdominal ring is exposed. An oblique incision through soft parts parallel to Poupart's ligament discloses the cord and its coverings. The operation can then be completed in the ordinary way.

After dealing with one side the operator exposes and treats the other in exactly the same way. By this manœuvre the time of the operation can be very materially reduced. In cases where it is desired merely to explore the opposite side this incision is particularly useful, and if no hernia be found the additional time taken is never more than one or two minutes. Such a necessity may easily arise in infants in whom the presence of a hernia on the opposite side is easily overlooked.

R. W. Murray, in his book,[1] goes so far as to say that 41 per cent. of young children with left inguinal hernia ultimately prove to have a right inguinal hernia as well. These figures would suggest that all cases of left inguinal hernia should be operated on by this method, so that the right side could be easily, rapidly, and adequately explored at the same time.

In conclusion, one last advantage may be mentioned. The transverse suprapubic incision does not, as a rule, involve the use of any artery forceps, as neither superficial epigastric, nor superficial external pubic arteries need be divided. By this means further time-saving is effected. Needless to say this method would not be adopted were any complication present such as irreducibility of the hernia or mal-descent of the testis.

## AN UNUSUAL CAUSE OF PNEUMOTHORAX.

BY BRANFORD MORGAN, M.D., M.R.C.P. Lond. & Edin.

ALTHOUGH instances of pneumothorax as a result of perforation of the œsophagus from malignant disease or chemical irritants are numerous, a search through the literature leads to the conclusion that

the accident to be described is worthy of being recorded.

W. G. M., a healthy man of 20 years, whilst dining on the evening of Nov. 25th, 1921, suddenly complained of a sharp pain across the chest, at the same time saying that he thought he must have swallowed something sharp. It was then recollected that the previous evening a glass sugar basin had been cracked. He was immediately given morphia by a doctor with whom he shared rooms, and was brought into a nursing home, where, at 9.30 P.M., an œsophagoscopic examination was made by Mr. N. S. Carruthers. No foreign body could be detected, but at the lower end of the pharynx an abrasion of the posterior wall was observed. The patient passed a restless night, with increasing dyspnœa, and when seen at 7.30 the next morning was sitting up in bed, very restless, extremely dyspnœic, and of livid countenance. There were the signs of a right-sided pneumothorax, with the apex beat of the heart in the fifth left interspace 1 inch outside the nipple line. Morphia was ordered hypodermically and oxygen administered through a nasal catheter.

Following these measures the restlessness became less and the respiratory rate diminished, but the cyanosis did not improve. His condition remained much the same until 6 P.M., when, as the dyspnœa and cyanosis were increasing, a needle was inserted in the fifth right intercostal space in the anterior axillary line. Much air escaped under pressure, and the apex came back within the nipple line. There had by now developed subcutaneous emphysema over and above the left clavicle and also above the right clavicle. Over the left lung air entry was somewhat diminished and coarse rattling râles were general. His condition gradually became worse and death took place at 3.30 A.M. on the 27th.

*Post-mortem Examination.*—The right pleural cavity contained about two pints of brownish fluid of neutral reaction, which was probably largely fluid taken by mouth subsequent to the accident. The right lung was collapsed. The left lung was congested and œdematous, some parts containing air. In the right posterior wall of the œsophagus at the level of the bifurcation of the trachea was a slit-like opening three-eighths of an inch in length, and placed vertically. The lower end of the opening gaped a little; the edge was clean-cut throughout. The fragment of glass could not be found and possibly passed on along the alimentary tract after damaging the œsophagus.

I am much indebted to Dr. F. W. Burton-Fanning and Dr. H. J. Starling for their advice on the case, and to Dr. D. S. Brough for performing the post-mortem.

Norwich.

# Medical Societies.

## MEDICAL SOCIETY OF LONDON.

### LEAD IN MALIGNANT DISEASE.

AT a meeting of this Society held on March 22nd, with Sir HOLBURT WARING, the President, in the chair, Prof. W. BLAIR BELL (Liverpool) read a paper on the Use of Lead in the Treatment of Malignant Disease, illustrated by photo-micrographs.

At the outset the speaker declared that it was not his intention to do more than briefly outline his general work on the subject in supplement of his contributions to THE LANCET and other journals, his chief purpose being to invite opinions and frank criticisms. The conversion of a working hypothesis into a substantial generalisation was, in his view, vastly more important than initial attempts at treatment; if that could be accomplished, some control of the disease, limited perhaps, must inevitably follow. He spoke of the very great amount of work which had been done on the subject by his colleagues in Liverpool. Chemical and physical factors were concerned in producing the chronic condition of the cell found in malignant disease, and perhaps the fibrosis in its neighbourhood. This condition might be described as some metabolic starvation, possibly an oxygen deficiency. Under these circumstances the cell must either recover or die. A third alternative, however, was that it might revert, in its efforts to live, to the ancestral type of trophoblast. When this latter process took place the cell eroded the maternal tissues. In cancer, the more malignant it was the more de-differentiated the cells were. Grown in vitro tissues removed from the body showed rapid de-differentiation. He proceeded to show that there was a great similarity between the cancer cell and the cells of the chorionic epithelium, based on the chemical constitutional factors, the chemico-physical state of the cell membrane, the physiological processes occurring in the different cells, and the similarity of the toxicological reaction to lead.

Prof. Blair Bell then showed the following table:

| | Water. per cent. | Phosphatides. | Phosphatide-cholesterol relation. |
|---|---|---|---|
| Normal tissue | 75·0 | 3·1 | 2·5 |
| Innocent neoplasm | 80·0 | 1·5 | 2·0 |
| Malignant " | 81·5 | 4·1 | 3·2 |
| Chorionic villi | 88·9 | 6·3 | 4·7 |

On the physiological side he referred to the brilliant work of Prof. Warburg, of Berlin, on the glycolytic power of various tissues, in which he showed that whereas the ordinary resting type of cell obtained its energy by oxidation processes, the cancer cell obtained its energy by the glycolytic process. This work had been shown to be sound by researches in the Rockefeller Institute, New York.

With regard to the toxicological side, the toxicological aptitudes of a cell depended largely on its chemical constitution and its physico-chemical state. It was found in 1907 that lead, given as an abortifacient, did not produce hæmorrhage of the uterus if given in proper quantities. Half a lethal dose of lead given to the mother would produce necrosis in the chorionic epithelium without causing in her any symptom. For a weight of 2000 g. 11 c.cm. (containing 0·1 per cent. of lead) of the colloidal preparation caused no symptoms. The effect of the lead was to cause a coagulation-necrosis. For the purposes of treatment it was found better to give massive doses, but dosage could never be generalised, as the tolerance and susceptibility of various patients varied so enormously. It was a striking fact that though there might be an occasional case of cancer among workers in lead, it was of the utmost rarity, and Hoffman, in America, reported that out of 25,000 certificated cases of lead poisoning there was not a single case of cancer. It was of no avail, in answering Prof. Blair Bell's assertion on this matter, to take figures from among workers in the potteries, 80 per cent. of whom never went near lead.

Speaking generally, said Prof. Blair Bell, a large body of the lay public were naturally searching and hoping for what they spoke of as a "cure for cancer," but there could never be a cure which would be applicable to every case, especially as so many cases died within a very few days of presenting themselves for treatment. Early recognition was acknowledged on all sides as most important, and allowance must be made for the fact that in very many cases radium, X rays, and other measures had already been tried. He and his co-workers fully appreciated that lead was a dangerous drug with which to work, and that was why there had been a very careful advance, and a refraining from publishing dosages, which might not be applied with due regard to all the conditions in a case. Their object had been to set up a real, sound, dependable generalisation, so that other researchers might start from that platform and test other substances in the treatment of the disease, for he did not claim that the lead treatment was perfect.

Dr. L. CUNNINGHAM (Liverpool) said that during the last two years he had been associated with Prof. Blair Bell in the work on this subject, and during that time they had had a unique opportunity of studying the effects of lead poisoning, which had a bearing on the lead treatment of cancer, and also of the effects of industrial lead poisoning. Renal and hepatic efficiency tests were carried out, and the effects of various doses were carefully measured and estimated. The age of the patient was important; younger patients did not tolerate lead well, and males bore it better than females. If there was no cachexia, where the growth was a large one, it was usual for the patient to tolerate lead well. Chemists had shown that there was a larger quantity of lead in a malignant tumour than in normal tissue of an individual who had been treated with lead. Also, after 0·15 g. of lead had been given, a relatively large amount of lead was excreted in the urine, but not more than a trace could be found in the fæces. The blood changes following the giving of lead were very definite, including a stippling of the red cells, a polycrasia, poikilocytosis; and the anæmia was marked by a diminution of the hæmoglobin rather than by a diminution of red cells. In some of the patients the anæmia was so pronounced that transfusion had to be resorted to. In only 4 of 200 cases under treatment was the blue line on the gums found. From June, 1924, the small doses of lead used were replaced by large doses, as with the former there had been cumulative effects, sometimes of a serious character, whereas with the larger doses, 0·15 g., the symptoms were produced rapidly and were quickly recovered from, leaving apparently no permanent damage. He concluded by describing a number of cases, with the aid of photographs.

Dr. J. G. ADAMI said he felt assured that Prof. Blair Bell's work in the last five years had been not merely empirical, but had a very definite scientific basis. He deprecated the idea that in this matter of combating cancer the central idea was and should be the determination of the cause; the great aim was arrest and cure. He was the greater benefactor to humanity who kept before him that higher goal, and was not satisfied with the thought that he was pursuing science for its own sake. Advances were not for the sake of knowledge, but for the service of mankind. He showed that this was the guiding principle actuating Pasteur. He, the speaker, felt sure that, varied as the causes of cancer might be, there was in that disease an essential disturbance of endocrine functions. The work which Prof. Blair Bell had now set out was really that of a group in coöperation, and he favoured an extension of that, so that every stage of the investigation could be adequately checked.

### *Discussion.*

Sir LENTHAL CHEATLE said he had always found Prof. Blair Bell to be a man of the greatest integrity who was doing pioneer work in trying to discover the effects of poisons on tissue cells, but he objected to the comparison between the epithelium of the chorionic villi and malignant growth. The chorionic villi, he said, were not malignant growths, even though they might become metastatic in the lungs—a theory based upon such a parallelism seemed to him to be a fundamental mistake. He urged the careful analysis and examination of all statistics dealing with cancer. There were three great types of what Americans called outspoken carcinoma. One was that in which the patient was suffering from secondary visceral deposits; another was that in which that was not so, but enlarged glands in the axillæ could be assumed to indicate the spread of carcinoma to them; and the third was carcinoma—e.g., of the breast—in which there were no enlarged glands at all. In this third class, he was convinced, there would be a large percentage of cures, while in the first and second classes, coupled together, most of the cases must be regarded as hopeless.

Dr. C. J. BOND (Leicester) urged the necessity of continual research into the chemotherapy of cancer; for that reason he congratulated Prof. Blair Bell on his research with simpler chemical elements. It was necessary for that gentleman to show how the lead got to the cancer cells, and, if it got to them, what happened to the lead after it had been taken up by the cells. He, the speaker, had been feeding living leucocytes with various forms of lead, the leucocyte having been incubated from the blood stream. After ingesting the lead the leucocytes underwent a sharp metabolic downfall, and the question arose as to whether the lead attached itself to the lecithin element in the cell. If the cancer cell contained a higher lecithin co[illegible] than the cell of ordinary tissue, then there was presented a working hypothesis along which to advance.

Dr. A. LEITCH said that if Prof. Blair Bell's work had met with hostile criticism, if his cures had been met with incredulity—and even his methods had been subjected to very severe criticism—he had only himself to blame for it. The cardinal mistake was made when there was published in THE LANCET in 1922 an article blazoning forth cures and yet withholding from the medical profession any details as to what the treatment was carried out with. It was said then, and it had been said ever since, that the matter was still in the experimental stage, that it was on an experimental basis, and from that day to this the method had never been disclosed. There was an apologia published in the *British Medical Journal* recently, signed by J. E. Smith and Dr. Adami, saying, in reply to an accusation that the method had not been disclosed, that so long ago as February, 1924, Prof. Blair Bell had described and discussed the method of preparation of colloidal lead. This statement could only refer to an article published in THE LANCET in February, 1924, particularly in regard to heavy lead suspensions. On March 13th last Prof. Blair Bell wrote that the whole method had been described and discussed two years ago in sufficient detail for anyone to have repeated and extended the work already done. It was, therefore, a surprise to him now to hear that the method had been published. He was surprised that Dr. Adami should have allowed his name to be used in the manifesto. Dr. Leitch repeated that the details of the method had not been given. The apologia in the *British Medical Journal* stated that in order to preserve the public from the serious risks the remedy would undergo if medical practitioners had it for use, the committee had been compelled to protect the method of manufacture, as had been done in the case of insulin. A provisional specification had been applied for; but a search of the register did not disclose what the remedy was. The specification was dated Oct. 26th, 1925, and its title was "Improvements in the Manufacture of Therapeutic Products." The speaker would not enter into the laboratory side of the matter, as no laboratory man would regard this as anything but most flimsy and inconclusive. And what about the cures? In THE LANCET recently Dr. Adami vouched for the fact that he had seen 30 previously inoperable cases of cancer cured (Dr. Adami: I did not say "cured"). But there were no recurrences. Up to that time Prof. Blair Bell himself only claimed 31. Observers differed a great deal as to what happened in the cases, and the speaker quoted a number of these disparities. In one of the cases, he said, if it was the intention to illustrate it by a microphotograph, he would have selected a portion of tissue which was less suggestive of mere inflammation. He was, he said, very sceptical about the whole matter.

Mr. CECIL JOLL said he felt that Prof. Blair Bell had been far too apprehensive about the risks involved in giving the details of his methods to the profession. He might be right in regard to entrusting it at present to the general body of practitioners, but he could long ago have safely entrusted it to properly organised institutions, such as existed in London and other large towns. Then figures could have been based not on 227 cases, but, in the case of so widespread a disease, 20,000 cases, and they would have been of real value. The London Cancer Hospital alone last year treated over 2000 new cases of cancer. He urged Prof. Blair Bell now, for the sake of humanity, to give every possible facility to properly organised institutions to test the method fully, and issue a report in a year or two.

Sir WILLIAM WILLCOX admired the great care which had been exercised in this research by Prof. Blair Bell. The remedy chosen was one of the most powerful and dangerous poisons known; it readily combined with the tissues, and was very slowly excreted. In one case lead continued to be excreted 12 months after all contact with lead had ceased. When absorbed by the mouth the damage it caused to the tissues was, he thought, irreparable. He took it that the reason frequent small doses had been replaced by larger doses was the following. When given intravenously a certain amount, *x*, was fixed in the body, and a certain quantity, *y*, was excreted; that the ratio $x : y$ was greater with the small dose than in the case of the larger one—i.e., in the latter a larger proportion of lead was got rid of and less permanent damage accrued. He asked whether, in the cases treated by Prof. Blair Bell years ago, there had been any changes in the blood pressure or in the renal or hepatic function. Lead might prove a powerful remedy, but it was a double-edged weapon, and there was need for a prolonged investigation, so that doses might be given—as they had been and, he hoped, would be with even greater success—so that the lead would act on the cancer cells without producing harmful effects on the healthy body tissues.

Mr. DUNCAN FITZWILLIAMS acknowledged Prof. Blair Bell's honesty and his high ideals in his scientific work, but there were features which were disquieting to the speaker, and, he believed, also to the profession at large. He considered that the danger of toxicity in this matter had been exaggerated. A large number of patients had been treated by the method, and Mr. Coke told him there were no bad effects. He, Mr. Fitzwilliams, had also treated a number of cases with no ill-results. But there was no declaration by Prof. Blair Bell as to the preparation he used. So slight was the trouble which the speaker experienced in his cases that he had passed the remedy on to four practitioners. If this method was to be of real value it must be passed on to the general practitioner. He would have felt much more reassured as to the treatment if Prof. Blair Bell had brought along a chorus of young surgeons to testify to it, because the statistics of any one man were of but little value. Recently a statement had been made that 100 cases of prostatectomy had been done without a death, and no one accused such a person of lack of faith. As the blood changes, &c., were so important when giving such a substance as lead, he looked in the literature for particulars, but looked in vain, and therefore he asked Prof. Blair Bell himself for information, but received very little. He then asked to be shown the work and was told in reply that he could come if he represented a society or body. Lister, on the other hand, welcomed everyone to come and see the results of his work. Carcinoma had been the happy hunting ground of the objectionable person in the profession who always hedged his activities round with some secrecy, and he feared he must say that Prof. Blair Bell had fallen under that ban. He did not consider it had been wise of that gentleman to refuse to show interested colleagues his methods.

Mr. W. F. COKE said he had found Prof. Blair Bell's work of intense interest and congratulated him upon it and on the way in which he had set about proving his surmise to be correct. With Dr. J. B. Cook he had been using lead for two years and had recently published his earlier results.[1] But two years was a short time in which to judge of results in such a disease. A long time was occupied in arriving at the most suitable dosage. He quoted a case in which the effect of the lead on the growth had been remarkably good, though, unfortunately, that patient had recently succumbed to acute bronchitis. He thought there should be team-work on this subject at every large hospital, the effort constantly going forward to find a drug, easily tolerated, which would cure the disease without causing much upset of the body processes.

Dr. G. R. LYNCH said that Mr. Coke and he had worked with lead and had encouraging results from it, the cases having been seen by Mr. Lionel Norbury.

Mr. F. A. G. JEANS (Liverpool) said the first case of which slides were shown by the opener was under him, and in regard to it the general view was that the cancer was inoperable. He had not been associated with the team who were carrying out this research, and he was glad to know the subject was to be ventilated. As a result of what he had seen of Prof. Blair Bell's work, he wished to pay a tribute to the sincerity of it.

Mr. LIONEL NORBURY supported the remarks of Mr. Coke and confirmed the description of two cases.

The PRESIDENT conveyed the Society's thanks to Prof. Blair Bell for having come forward to discuss the subject.

### *Reply.*

Prof. BLAIR BELL, in reply, paid a tribute to the excellence of the chemical and pathological work which was done in the research by his colleagues in Liverpool. He was convinced that it was useless to look for a single cause of cancer, but the important matter was to realise the specific process of de-differentiation of cell, which had been damaged in a variety of ways. He was dresser under Sir Lenthal Cheatle, and his tendency was to pay great respect to what he said, but in the matter of the characters of the chorionic epithelium, he considered that his remarks were wrong and unjustifiable. The malignant growth of the chorion did not take place in the presence of the live fœtus, but only after the fœtus was dead. It was for that reason he searched for a biological hormone, and he went on to the use of lead. A benign growth was a hyperplasia of normal tissues; a malignant growth was a de-differentiated growth back to the chorionic type. After Dr. Bond's remarks a search would be made to see if any change was produced in the red blood-cells. Lead inhibited all growth processes, growing cells as well as other tissue. The influence of lecithin and of phosphate of lead had not been forgotten; lead replaced calcium in bones.

He found it very difficult to deal with Dr. Leitch's remarks adequately, but the colossal ignorance of some of the critics of the method was deplorable. It was untrue that he did not publish the method two years ago, but it was then assumed that everyone knew the method of making colloids; what he did was to employ the ordinary sparking method between two naked electrodes. He felt that, in dealing with such a serious subject as this, Dr. Leitch's speech was quite unpardonable in its character. He (the speaker) had worked at this matter, at his own cost, for a number of years, and when the Association of Surgeons met in Liverpool he gave a demonstration, and every laboratory was open to members of that society. He was under the impression that Mr. Fitzwilliams's name was put down to be notified when he could come, and he knew that at the time everybody was exceedingly busy. He had published a good deal of work, and the charge of secrecy ought never to have been made against him. It must not be forgotten that many of the cases sent to his colleagues and himself for the treatment were those which had been given up by surgeons. He was well aware of the potency of the drug being employed, and that was why he had not been in a hurry to disclose exact particulars before every possible test had been made. The slight discrepancies as to dates and size of tumour might occur in the narration of any series of clinical cases, and the merits of the treatment did not suffer from that kind of criticism.

---

SCOTTISH HOSPITALS EXTENSIONS.—The managers of Edinburgh Royal Infirmary have agreed to purchase for £90,000 the buildings and ground occupied by George Watson's College in Archibald-place for the extension of the hospital. An "influential citizen" has aided the purchase, which had begun to look hopeless, by a donation of £10,000.—The £75,000 which is estimated to be the cost of extensions of the Glasgow Royal Hospital for Sick Children has been subscribed in less than six months by 1000 *contributors* only. When the enlargements are complete the hospital will contain 100 cots, which is said to be the largest number in any similar institution in the world.—It is proposed to provide more accommodation for the maternity department of Dundee Royal Infirmary at a cost of £30,000.—A conference in Edinburgh last week discussed the possibility of establishing a Scottish scheme for the treatment of cripples, and appointed a representative committee to formulate a plan.

# HUNTERIAN SOCIETY.

At a dinner meeting of this Society, held at Simpson's Restaurant, Cheapside, on March 22nd, Dr. Howard Humphris, the President, being in the chair, Dr. R. A. Gibbons opened a discussion on

## Sterilisation of the Mentally Unfit.

He included in the term "unfit" anyone who through moral as well as mental deficiency failed to conform to the ordinary convenances of society. He quoted statistics showing the increase in the number of mental defectives under both statutory and voluntary supervision, and the annual cost (about £4,000,000) of maintaining the country's prisons.

*Heredity.*—His object was, he said, to suggest a method of diminishing in the future not only the mentally deficient, but the number of persons in prison, and to prove that some such means of treatment should be adopted in the interests of the State. The study of heredity, "the genetic relation between successive generations," was vitally important, for it was the main cause of both mental disorder and crime. It was also the factor which made the consideration of mental deficiency so disappointing, for, in the experience of superintendents of institutions, the degenerate, the feeble-minded, and the imbecile would remain as they were, no matter what was done for them. According to Dr. Paul Bowers, 44 per cent. of convicted prisoners were psychopathic. Environment was not to be ignored altogether, but a good environment could not make up for inherited deficiency, and this was the essential factor in criminal conduct. Authorities varied in their estimates of the percentage of prisoners with malign inheritance, but it was at least twice that of the normal population. The actual brain pathology of mental deficiency or habitual crime was, however, obscure.

*Environment.*—There was no doubt, continued Dr. Gibbons, that environment exerted a powerful influence upon the young, and some philosophers had taught that all men were born equal and became unequal later through the inequality of their opportunities. The nervous system was modified by adapting to the environment, but the organism must possess fundamental qualities that determined its adaptability. There would always be difference of opinion about whether "nature" or "nurture" were the more important. Conklin said that the modifications produced by environment were insignificant compared with hereditary disposition; Lacassagne that the microbe (the criminal) was only of importance when it found a bouillon in which it could grow, and that societies had the criminals they deserved. It was true that some mental defectives had healthy parents and owed their condition to bad conditions at or before birth, or to accident or illness afterwards, but the large majority inherited their deficiency.

*Treatment.*—Mental defectives must, he said, be treated either by segregation or by sterilisation. If segregation were thorough and included all cases nothing could be better, but it was impossible to segregate many girls and boys who were quite well enough to be kept at home. It was these highest grade defectives who were the source of danger. Apart from that there was not sufficient accommodation for many hundreds of urgent cases, who were a menace to the community as long as they remained at large. Defectives bred from six to ten times as quickly as normal people, and the Royal Commission on the Care and Control of the Feeble-minded found that to prevent them becoming parents would largely decrease the number of these persons in the population. Segregation being ineffective, the only method of diminishing their propagation was to sterilise them. The operation was simple, and in no way interfered with metabolism or sexual feeling. It would release large numbers from segregation. The limit age should be set at 16, for if there were no evidence of improvement by this time there never would be. A patient would only be sterilised after very careful deliberation by an alienist and the medical officer in charge. Sterilisation would make no difference to promiscuous intercourse, which would always go on, but it would prevent children being born with syphilis or gonorrhœal ophthalmia.

Young or middle-aged criminals with a neuropathic inheritance who had been convicted more than twice should also be sterilised, as a eugenic and not a punitive measure, though it might in time be looked on as an added punishment. This was apart from castration as a punishment for sexual offences. Dr. H. C. Sharp, of California, had seen no unfavourable symptoms, mental or physical, in 236 patients after vasectomy. Experiments had been made in 15 of the United States; in nine the law was still in force and in six it had been set aside as unconstitutional or repealed.

Sterilisation might be performed with X rays if they did not interfere with the functions of the interstitial cells. At present it was effected by vasectomy in the male and division of the Fallopian tubes in the female. Neither operation was cruel or dangerous, and this measure would lessen in time the numbers of mentally deficient, would also diminish the number of convicts, and would thereby relieve the community of their bad moral influence and the State of part of the great burden of maintaining them.

### *Voluntary Sterilisation.*

Mr. Harold Cox dealt with the political and practical, as opposed to the scientific aspect of the problem. He said that the opponents of sterilisation did not realise that the dangerous defectives were those who were not bad enough to shut up. Mental defectives were bound to pass the taint to their grandchildren, if not to their children, and it was a gross injustice that they should be allowed to have any. They were on the increase, and sterilisation would do something to reduce them, even if it did not solve the whole problem. He was surprised that Dean Inge, a man of detached and impartial mind, should advance the argument that, if they were sterilised, they would be set free to commit rape and spread disease. They could do that now. Any defective free to remain at home was free to produce a tainted child, and the opponents of sterilisation could not propose to lock all, even the highest grade feeble-minded, up for life. Some held that sterilisation was disgusting, but it was no more so than any other surgical operation. There was nothing sacred about procreation; the lowest animals were the biggest breeders. The Roman Church opposed sterilisation and birth control on these grounds, but itself held up celibate priests and virgins as the highest types of humanity. Surgical operations were undertaken to protect individuals; why not the community? He did not advocate compulsory sterilisation, but proposed that those defectives who were sufficiently sound to realise that they should not have children should be given facilities for undergoing sterilisation at the public expense, and that parents and responsible guardians of others should be able to bring their children or wards for treatment without meeting, as they did now, the opposition of the law. Parents of defective children often asked doctors to sterilise them.

### *De-Sexualisation.*

Dr. Reginald Worth said it must be understood that sterilisation meant two things: ordinary vasectomy and castration. Plato had urged castration as a punishment, and the idea still appealed to many people. Only nine of the original 15 American States had retained their sterilisation laws. The clergy had been the principal objectors, on the grounds that the measure made the man on whom it was practised an outcast, and interfered with his life, liberty, and pursuit of happiness. Those with experience of double ovariectomy said that it produced an artificial menopause with an almost incurable melancholia. He warned his hearers that if there were no mentally deficient the world would be a pretty poor place, for its real drudgery was done by people who were slightly defective. It was a fallacy that to sterilise the unfit would produce a perfect race, for defectives were often the offspring of healthy parents. The failure of the mother to produce an abortion often had a very bad subsequent effect on the child, and modern methods of birth control were causing an increase of involutional insanity among women. He thought that a great deal of discussion would still be necessary before sterilisation could be put into practice.

The **President**, as a radiologist, speaking of the interference of X rays with the interstitial cells said that although the spermatozoa were destroyed the sexual potency was increased. X rays were a third method in addition to vasectomy and castration. They might produce a melancholia, but so might the natural menopause.

### *Discussion.*

Sir **Bruce Bruce-Porter** said that he was anxious that the public should not get the impression that castration and ovariectomy were suggested methods of sterilisation. The Church's opposition could not be taken seriously by medical men as the Church had consistently opposed progress from the earliest times. Because a deficient child was born from healthy parents that did not preclude the possibility of unfitness in the grandparents. When a man was charged with murder there was often plenty of evidence of insanity in his family history, but parents would rarely admit to it. Mental deficiency accounted for a large number of people living in comfort at the State's expense, and they received a good deal more sympathy than the struggling fit man.

Mr. E. **Mortimer Woolf** complained that the discussion till then had been purely idealistic. Figures could prove anything, and heredity was an uncertain thing. Operations were not undertaken to protect but to benefit the health of individuals. Otherwise every babe would be circumcised and have its tonsils and appendix removed in its first week of life as a matter of course. He regretted the tendency of the discussion to assume that the medical profession should dictate to the public who should be sterilised and assist the law to sterilise people against their will. The profession were the advisers of the public. We did not know that a patient did not suffer as a result of having the Fallopian tubes severed. A kidney atrophied when the ureter was cut, and a testis might do the same. Many careful animal experiments were necessary before these methods were advocated for the human race. We were apt to get carried away by our ideals and create other hells that we knew not of.

Dr. B. **Dunlop**, referring to the recent leading article in The Lancet (March 13th, p. 501), denied that the advocates of sterilisation promised a rapid cure, but agreed they had not faced the point made by the article, that in order to tackle the problem of sterilisation it was necessary to tackle the whole problem of heredity.

Dr. **John Adams** said that the State would soon be forced to tackle the problem of heredity and disease. Many old and disabled people were not treated nearly so well as deficients, who were allowed to multiply freely and who inevitably produced deficient progeny. Many "healthy parents" of idiots had syphilitic parents themselves. In the animal world a balance of power kept a dangerous species from getting too strong, but we did not possess it. We should do something at once. People who were deficient in judgment and responsibility would not present themselves for sterilisation voluntarily. Venereal disease in the mentally deficient was the factor that killed off bad stock in a few generations and restored the balance of power.

Dr. W. **Langdon Brown** asked what the effect would be on the happiness of the human race of eliminating the deficient. Darwin's family tree had mental deficients in nearly every generation, and if sterilisation had prevented his birth the world would have been permanently poorer.

Dr. **Bernard Myers** quoted Dr. Tredgold as saying that even if we sterilised every mental deficient we should not wipe out deficiency, for many "healthy" people were carrying the taint. Moreover, sterilisation would give many of them a grudge against the world.

Dr. J. **Dundas** said that the large majority of military prisoners in the war were mentally deficient, and the school inspector found tame idiots in every village school, whose mothers were tame idiots.

Dr. F. L. **Provis** held that X rays produced the same effect as double ovariectomy and should never be used.

Dr. **Thomson Brown** said that Darwin might still have been born, even if sterilisation had been in force.

Mr. H. S. M. **Grover** pointed to the analogy of prohibition as an argument against force and advocated patient work at general hygiene.

Dr. C. P. **Blaiker** suggested that to follow the methods of Nature would be to kill our mentally deficients instead of segregating them.

Dr. H. A. **Ellis** deprecated our encouragement of the breeding of mental defectives and our stabilising of the fit with methods of birth control. Sterilisation, however, would only touch the fringe of the problem and was undesirable.

Dr. **Gibbons** replied.

# SOCIETY OF MEDICAL OFFICERS OF HEALTH.

## CANCER FROM VARIOUS POINTS OF VIEW.

A meeting of this Society was held on March 19th, when Dr. G. F. **Buchan**, the President, took the chair, and a number of members and visitors contributed to the discussion on this subject.

### *Cancer and the Public Health Administration.*

Dr. W. D. **Champneys** (assistant M.O.H., Willesden) said that the United States was far ahead of any other country in the campaign against cancer. The American Society for the Control of Cancer, founded in 1913, had done excellent work in collecting, collating, and disseminating information. It conducted a general education campaign with lectures, articles in the press, cinemas, wireless talks, posters, circulars, handbooks, a periodical, and private correspondence; it held special campaigns periodically, such as the National Cancer Week of 1921; and it promoted the establishment of cancer clinics to secure prompt diagnosis and treatment. Education of the medical profession was an important part of its work, for it was estimated that even in 1923 10 per cent. of the doctors consulted for cancer of the breast delayed on an average 25·9 months per case before recommending operation, and often no local examination was made at the first visit. The Pennsylvania Cancer Commission had found that the average time between the discovery of symptoms and the first call on the doctor had fallen from 18 months in 1919 to 14·6 months in 1923, and the Society believed that its propaganda was proving successful.

Describing the measures taken by the British administration, Dr. Champneys said that the Ministry of Health had set up a Departmental Committee in 1923, which had issued four memoranda as a basis for work by local authorities. It had also organised an inquiry into mammary cancer in a number of centres. The efforts of local authorities were at present confined to certain large towns, where cancer committees had been formed at the Ministry's suggestion. At Manchester, for instance, a committee undertook continuous supervision of all the cancer cases, and there was a complete system of records in hospital and private practice, with histological examination of specimens wherever possible. Leaflets urging the public to consult doctors for certain symptoms had been issued in several large towns. From 1914 onwards Dr. Mearns Fraser had published a large number in Portsmouth and had been told by surgeons that some patients came earlier in consequence. As far as Dr. Champneys was aware no public lectures on cancer had been given, though a Cardiff committee had suggested health talks to girls leaving school about the possibility of cancer in later life. Finally, an attempt had been made by the Ealing Guardians to start a cancer clinic at an infirmary, but this had come to nothing because the existing Poor-law did not cover such work.

What measures, then, should local authorities take in the future? Many ways of attacking cancer had not yet been tried in this country. First there was education, both of the medical profession and the public. There was a backward 10 per cent. of doctors in this country who needed, and would welcome, further information, which they might gain from a booklet from the Ministry of Health, from meetings of medical practitioners convened by local authorities or cancer committees, or from post-graduate lectures and demonstrations (as already suggested by the Ministry). Leaflets, posters, advertisements, articles, lectures, and cinema films issued by the Ministry were suitable means of influencing the public. There remained the need to secure accurate diagnosis, and he strongly recommended a trial of cancer clinics which should provide free diagnosis for anyone caring to attend. They should be set up either in good general hospitals or in existing municipal hospitals or clinics; the surgeon should be a man to whom local doctors would willingly bring their cases for consultation; and there should be arrangements for X ray examination and temporary admission for diagnosis. As for treatment, there should be better facilities for taking patients to treatment centres.

### *The Surgical Point of View.*

Prof. G. E. GASK (St. Bartholomew's Hospital) said that probably a good general surgeon, given proper equipment and the coöperation of a radiologist, ought to make a correct diagnosis of cancer in 90 to 95 per cent. of cases. There was no doubt that the most effective treatment of malignant growths was complete and early removal. Many other methods—e.g., radium and deep X rays—had given some remarkable results, but it was not yet clear under what conditions they could be relied on. Until further research had produced more definite information, the thing to aim at was early removal following early diagnosis. Unfortunately, the results of operation were on the whole bad; but it was difficult to be definite about them because statistics were not kept in a business-like way. Surgeons who were asked about the prognosis of this or that operation generally had to rely on their own impressions and their own cases, and it was desirable that the statistics of the various hospitals should be kept in a uniform way. Immediate results were of little value, and central authorities should ask every hospital to start follow-up schemes so that exact information about a large number of cases should become available.

### *Laboratory Work.*

Dr. W. D. NEWCOMB (assistant pathologist, St. Mary's Hospital) doubted whether 90 per cent. of cases could be diagnosed by the surgeon. It was a mistake, he said, to ask for a pathologist's opinion only in difficult cases. An apparently simple cyst from the breast might show malignant change under the microscope, and the border-line between innocent hyperplasia and cancer was none too easily defined. The pioneer work of the Imperial Cancer Research Fund under Bashford and Murray was now beginning to bear fruit. Gye and Barnard had offered a solution which explained many of the known facts about cancer, and their work should be confirmed or disputed shortly. The investigations of Lumsden suggested that a serum might possibly be produced which would cure mouse cancer, whilst Maud Slye's work on mice, which indicated that susceptibility to cancer was a Mendelian recessive characteristic, had been so far accepted that American eugenists were recommending people of cancerous heredity not to inter-marry. Of Blair Bell's lead treatment it was too soon to speak.

### *Cancer and the General Practitioner.*

Dr. F. E. ALLEN said that on going into general practice after some years of hospital appointments he had found that his ideas on the value of signs of cancer were rudely knocked on the head. In his practice cancer accounted for 14 per cent. of the deaths, but less than 1 per cent. of the visits. It was very difficult for the practitioner to spot one grave symptom amongst a plethora of others. Having been taught as a student that piles in a middle-aged man suggested carcinoma, his partner had examined the rectum of every such case for 25 years, but none had been malignant. The cancer patient often had toxæmia which gave him vague aches and pains masking the lumbago or sciatica of vital significance. And his doctor might have attended him for much the same symptoms for years.

Women were getting much more sensible about cancer of the breast; working-class women often came for an opinion. It was, he thought, always a good thing for a doctor to get a second opinion about the condition of the breast. Women were also more alive to the significance of metrorrhagia after the menopause, but this symptom did not always indicate cancer in spite of what authorities said. The general practitioner had to be very wide awake to avoid missing cancer, and there were often economic reasons why fathers and mothers of families did not dare to consult a doctor until too late. Wealthier patients, on account of a growing feeling among them against registered practitioners, tried a course of diet from an unqualified healer or went to an osteopath. In fact, the panel patient, who had to see his regional medical officer if unwell for a few weeks, was really safer than the richer patient.

Cancer clinics, Dr. Allen believed, were undesirable, for the public had enough wind up already. Little could be told about cancer, as the cause was not known and people already knew that the outlook in cancer was very bad indeed. Regular medical examination every six months would, however, be really useful. Could not the big insurance companies be induced to arrange this for policy-holders without charge? It would probably pay them to do it.

### *Discussion.*

The PRESIDENT expressed his warm interest in this proposal and invited discussion.

Dr. W. J. HOWARTH said that he was loath to recommend ad hoc institutions for dealing with cancer until knowledge was more definite. It would be easy to magnify the importance of such places and drain resources from other channels. There was more than a little truth in the idea put forward by Mr. Morley Roberts in his recent book, "Malignancy and Evolution," that there is a place in cancer research for the fireside philosopher. Perhaps good might come of study by a group of members of the Society who could meet to discuss the work being done in the various fields.

Dr. LOCKHART STEPHENS said that he had addressed over 7000 people at lectures in eight English towns on what ought to be known about cancer, and had found them very appreciative. It was ignorant fear, not knowledge of the truth, which frightened people. Leaflets did not go for much in this country, but they might influence general practitioners, who, in their turn, could work to the best advantage because people knew and trusted them. He thought that surgeons at big hospitals took an unnecessarily pessimistic view because many early cases were efficiently dealt with by local surgeons and never went to central hospitals. It should be known that cancer is curable and that the chief obstacle to its being cured is the obstinacy of the public in not coming for early diagnosis. *Lectures certainly did good.*

Dr. CHAMPNEYS, in reply, said that public panic should not be feared; it was due to lack of knowledge rather than too much. Only genuine facts should be told and not theories. Several large assurance companies in America insisted on periodic examinations of their policy-holders, such as Dr. Allen had suggested. It was one of the terms of assurance. In conclusion he pleaded again for special clinics. General hospitals were often too far away from the patients, and people were now accustomed to municipal clinics. If they could get the free opinion of an expert they would flock to see him; treatment was not an essential part of the scheme. General hospitals were already understaffed and overworked.

Dr. ALLEN said that leaflets to doctors would probably go the way of other circulars. Medical officers of health ought to be on close and pleasant terms with the practitioners in their district, when personal discussion would lead to the right facts being spread.

## JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.

### *The Pineal Body.*

ON March 9th Prof. P. T. Herring gave a lecture on the pineal body. After alluding to the numerous theories about its function put forward by anatomists and philosophers, he gave a brief account of the comparative anatomy of the organ in various types of vertebrates, from the elasmobranch fishes upwards. It is, he said, one of a series of structures associated with the roof of the third ventricle. Its construction and morphology suggest a secretory function; it has a distinct nerve-supply, and originally its cavity communicated with the cerebro-spinal canal. As development advanced it was shut off from this connexion, and apparently became an organ of internal secretion. In some of the lizards it is associated with the appearance of a mesial eye, but the structure and nerve-supply of this eye are distinct from those of the pineal gland itself. In the higher mammals, in which the gland is shut off from the cerebro-spinal canal, a mass of definite glandular epithelium, which is almost certainly secretory, is found immediately behind the pineal recess and lining the ventricular surface of the posterior commissure. The pineal body itself consists mainly of cells with characteristic club-shaped processes, and tumours of the gland are found to be either teratomata or pinealomata composed of these characteristic cells. Clinically, tumours of the gland appear to be associated with precocious sexual development. Experimental physiology has yielded contradictory results, but certain experiments based on feeding with the gland substance have produced precocious sexual development in young males; in females the results are negative. Extirpation experiments are extremely difficult on account of the vascular relations of the gland, and most animals die of hæmorrhage. Transplantation has never been successful. The posterior lobe of the pituitary body, Prof. Herring pointed out, resembles the pineal gland in its relation to the cerebro-spinal fluid system.

*Corrigendum.*—At the meeting of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine held on March 4th (THE LANCET, March 20th, p. 601) the paper on A Method of Endoscopy of the Uterus and its Indications was read by Mr. H. F. *Seymour*, of Brighton. We followed the printed diary card supplied by the Society and regret the inaccuracy.

---

THE LATE DR. C. L. FRASER.—Dr. Charles Lachlan Fraser, who died recently at Berwick, was a native of Montrose, where he was born in 1859. He was educated at the Montrose Academy and at the High School, Edinburgh. He studied *medicine* at the *Royal Infirmary, Glasgow*, becoming L.R.C.P. Edin. in 1885, F.R.C.S. in 1887, M.R.C.P. in 1893, and F.R.C.P. in 1895. In 1890 he took the D.P.H. Edin. Dr. Fraser spent most of his working life in practice at Berwick-on-Tweed, being a surgeon to the Berwick Infirmary and a school medical officer. He was keenly interested in local affairs as a justice of the peace and in the Territorial movement, holding rank as Lieut.-Colonel R.A.M.C., T.F.

BIOCHEMISTRY.

*Practical Physiological Chemistry.* Seventh edition. By SYDNEY W. COLE, M.A., Trinity College, Cambridge; University Lecturer in Medical Chemistry, Cambridge; Hon. Director of Pathological Chemistry, Charing Cross Hospital Medical School. Cambridge: W. Heffer and Sons, Ltd. 1926. Pp. 470. 16s.

MR. S. W. Cole is recognised as being one of the most experienced teachers of practical biochemistry to medical and biological students, and his writings have benefited by his wide experience. This book, first published in 1904, has grown enormously in size, and its present seventh edition bears but little resemblance to the earlier issues. Chapter I. is devoted entirely to physical chemistry—a new feature. An elementary account of the theory of solutions, hydrogen-ion concentration, and colloids is given. Mr. Cole has thereby solved the problem of many teachers, since the practical exercises and theoretical discussions are so clear that no special book or apparatus is required. The next two chapters deal with proteins, whilst the fourth is allotted to methods for the preparation of certain amino-acids. Here the author adheres in the main to the methods described in Abderhalden's Biochemisches Handlexikon; some of the more recent methods give very much better results, and one would hope to see the techniques of Hanke and Koessler and similar methods included in a new edition. Chapter V., on carbohydrates, contains little new matter, with the exception of the method devised by the author for the estimation of blood-sugar. Additions have also been made to the chapters on fats, foods, and enzymes. The omission of an account of the work on the optimum pH of diastase mars an otherwise excellent account of this ferment. An entirely new feature is Chapter IX., on biological oxidations and reductions. It forms one of the most concise accounts of this difficult subject that we have as yet seen. There are some additions to the account of blood pigments, but the information supplied is sketchy and not very practical. The final chapters are devoted to the analysis of blood and urine.

Some omissions are noticeable For example, insulin is not mentioned throughout the book. It is now so cheap that some practical exercises with it could properly be included. Indeed, all the internal secretions are entirely ignored. The author has devised many new methods to which his name is properly attached; certain other devices described are such slight modifications of existing recognised methods that perhaps unnecessary multiplication is likely to result from a special table. These points are mentioned with the hope that they may be of use when the preparation of other editions of this most excellent work is contemplated.

*Chemical Pathology.* Being a Discussion of General Pathology from the Standpoint of the Chemical Process Involved. Fifth edition. By H. GIDEON WELLS, Ph.D., M.D., Professor of Pathology in the University of Chicago and in Rush Medical College, Chicago; Director of Medical Research in the Otho S.A. Sprague Memorial Institute. London and Philadelphia: W. B. Saunders Company. 1926. Pp. 790. 40s.

THIS book has become a classic. We have had the pleasure of watching its development from the first edition, published in 1907; in all the earlier editions the author exercised a critical faculty for which he is noted, with the result that a masterly survey of the more reliable investigations and publications was produced. As time went on the amount of literature to be digested increased by leaps and bounds, and although the volume grew, the selection of matter for insertion evidently became more and more difficult. In the present edition there is much rather doubtful work recorded, and in some instances even work which has been contradicted appears in the text in authoritative tones. This is probably the result of the very speedy growth of the subject, making it a herculean task for one man to keep abreast of all its developments and checks, and the book remains still a very fine work even if the balance is less carefully held.

The first chapters deal with the physical chemistry of the cell and enzymes. The section on oxidation processes is rather disappointing, for although the thermolabile systems are well dealt with, glutathione receives a mere mention. With regard to diastase, there is no account of the recent work on the optimum pH for this substance. The next three chapters deal with the chemistry of bacteria, animal parasites, and various poisons. These remain very much as before, whilst the next four chapters on immunity contain much new matter. We would suggest that the author takes the Abderhalden reaction too seriously in devoting two pages of close print to it, but he is able to see the doubts cast upon its value. The chapter on growth and repair has been extended, and includes a very good summary of the present-day views on vitamins. The special chapter on œdema has been greatly expanded, and is undoubtedly one of the finest in the book. On the subject of pathological pigmentations, the part played by hæmoglobin is not set out clearly. The account of the disintegration products is rather sketchy, especially as regards hæmatin.

The section on ductless glands is perhaps the least successful in the book. For instance, the author gives the impression that the isolation of thyroxin has rounded off all chemical researches on the thyroid; yet many reliable workers have pointed out that thyroxin does not constitute the total iodine of the gland. Again, the formula proposed by Kendall is by no means a generally accepted one. The author describes Robertson's work on tethelin, but does not mention the counter observations of Cannon and Drummond. Prof. Wells, speaking of the reproductive glands, says, "too little is known as to the chemical character of these secretions to warrant their discussion in this place." This may be true in relation to the testicle, but the old observations of Herrmann and Fränkel, and the newer ones of Allen and Doisy on the ovary certainly deserve inclusion in any modern text-book on chemical pathology.

On the whole, however, the book retains its place as one of the greatest expositions of chemical pathology in the literature. If we may offer a suggestion, it is that the author would be well advised not to increase the size of future editions, but to exercise as keenly as in the past that excellent critical faculty that has made his writings so valuable.

### DISEASES OF THE EYE.

A Manual for the Practitioner. By HENRY KIRKPATRICK, M.B., Lieut.-Col. I.M.S. (retired); late Professor of Ophthalmology, Medical College, Madras. Calcutta: Butterworth and Co. 1925. Pp. 132. 10s. 6d.

THIS book is written for the general practitioner, especially one practising in remote parts. The author would hardly maintain that it contains sufficient instruction for those who have to undertake the responsibility of treating difficult eye cases. At the same time a comparatively small book of this sort will be of use to men who have learnt the elements of the subject in student days and who want to maintain their knowledge in order to be able to deal with emergency cases. Colonel Kirkpatrick's experience has been acquired in India, and, as one would expect, a good deal of attention is devoted to trachoma and its sequelæ. With regard to causation of cataract the suggestion is made that its frequent occurrence in India may have some connexion with the poor diet of the population, especially a deficient supply of vitamins. In the domain of treatment the book suggests a method of inspecting the upper conjunctival fornix which, so far as we know, is original. About 1 c.cm. of normal saline is injected beneath the conjunctiva at the upper border of the tarsus. This method, which the author calls "ballooning," might certainly be of service in cases where the ordinary method of eversion is difficult. Another original method of treatment applies to cases of acute conjunctivitis where there is much œdema, and especially the gonorrhœal form and septic cases. This consists of an eye bath of 10 per cent. magnesium sulphate applied for a few minutes every few hours. The author says "the hypertonic solution is able to exert a powerful osmotic action through the inflamed membrane, and thus to reduce the chemosis and to relieve the lymphatic circulation." The suggestion has been favourably mentioned in recent editions of some of the larger text-books—De Schweinitz and Fuchs.

Altogether a useful little book.

### LECTURES ON NUTRITION.

London and Philadelphia: W. B. Saunders Company. 1925. Pp. 243. 12s.

THERE is more important scientific matter packed into this slender volume than is to be found in many closely-printed tomes. It is a series of lectures given at the Mayo Foundation and at the Universities of Wisconsin, Minnesota, Nebraska, Iowa, and Washington. The first lecture, by Dr. F. G. Benedict, deals with basal metabolism; in the second Prof. Graham Lusk discusses problems of metabolism; whilst in the third Prof. E. F. Du Bois writes on the proportions in which protein, fat, and carbohydrate are metabolised in disease. Prof. A. V. Hill, in the fourth lecture, deals with muscular activity and carbohydrate metabolism, and the two final lectures, by Prof. E. V. McCollum and Prof. H. McLean Evans, are devoted to vitamins and kindred bodies. These essays do not make easy reading; they are too advanced for any reader without knowledge of biochemistry. But it is rare to find a collection of essays in which such broad generalisations have been drawn with great erudition and skill. Particularly would we commend the lecture by Prof. Lusk, who reviews past and present chemical and physiological knowledge in a manner worthy of our scientific ancestors, and, let it be added, in a manner rare in an age devoted to hasty inquiry into minutiæ. An admirable series of references is given at the end of each lecture which further enhances the value to the student of this welcome book.

### DISEASES OF THE NOSE, THROAT AND EAR.

Fifth edition. By WILLIAM LINCOLN BALLENGER, M.D., late Professor of Otology, Rhinology, and Laryngology, University of Illinois, Chicago. Revised by HOWARD CHARLES BALLENGER, M.D., Otolaryngological Staff, Evanston Hospital, Chicago. London: Henry Kimpton. 1925. Pp. 1080. 42s.

Ballenger's work on diseases of the nose, throat and ear has long been recognised as one of the foremost text-books on the subject, and this, the fifth, edition is evidence of its continued popularity. The number of alterations and additions in the new edition are not very great. The description of the Ballenger-Sluder method of removing the tonsils has been rewritten and new illustrations inserted, and it is noteworthy that Ballenger no longer uses the alveolar eminence to push the tonsil through the guillotine, as advised by Sluder, but employs the index finger of the other hand; this is the procedure originally described by Whillis, of Newcastle, a few months before the publication of Sluder's work, but he does not mention Whillis's name (v. THE LANCET, Sept. 17th, 1910, The Enucleation of Tonsils with the Guillotine, by S. S. Whillis and F. C. Pybus): Lautenschlager's and Halle's operations for the treatment of atrophic rhinitis by advancing the antro-nasal wall are described, but the results of these methods are not given. The chapters on hay fever, hyperæsthetic rhinitis, and asthma have been rewritten, as also that on Ménière's symptom-complex. Much attention is given to operative procedures, and not quite enough to their indications and results; indeed, the criticism may be offered that too many operative methods are described, and that the student is not given sufficiently dogmatic guidance by the authors as to which of the methods is to be preferred. A good instance of this is the chapter on the surgical correction of obstructive malformations of the nasal septum. Here an immense number of methods are described, many of which, such as Asch's and the spokeshave operation, are really obsolete. Few will agree that a simple spur may be removed with a saw or spokeshave with less risk to the integrity of the septum than by submucous resection; on the contrary, most believe that a spur is nearly always but the apex of a deviation. It is not a good reason for preferring other methods to submucous resection, that "they are simpler and almost, if not quite, as satisfactory in their results." Of the surgical treatment of malignant tumours of the tonsil, the only method described is von Langenbeck's temporary resection of the lower jaw, and the possibility of removal through the mouth is not mentioned. There is no mention of the use of vocal rest in the treatment of tuberculous laryngitis. However, in spite of inequalities, difficult to avoid in a work of this size and scope, this is an admirable text-book full of valuable information.

### Plastic Surgery of the Nose.

By J. Eastman Sheehan, M.D., F.A.C.S., Plastic Surgeon and Chief of Nose and Throat Clinic, New York Post-Graduate Medical School and Hospital. New York: Paul B. Hoeber. 1925. Pp. 240. $10.

In this book Dr. Sheehan confines himself to the plastic surgery of deformities of the external nose, and deals with the treatment of such conditions as twisted and "hump" nose, depressions of the bridge, deformities of the alæ and tip, and, finally, with rhinoplasty for the correction of complete or extensive destruction of the nose. He does most of his work on the nasal bridge through an incision which splits the columella, and claims that the resulting scar is almost invisible; and he rightly emphasises the importance of providing an epithelial lining for the interior nasal cavity in all forms of rhinoplasty where the original lining has been destroyed. He acknowledges "cordially and gratefully" the influence of Mr. H. D. Gillies, whose work he had the opportunity of observing over a long period at Queen Mary's Hospital at Sidcup. In his opinion, the use of paraffin for the correction of disfigurements cannot be too strongly condemned; but it is a pity that he allows himself to say that all who use this method are either ignorant or influenced by considerations of personal gain. This kind of argument is of no value on a scientific question. As a matter of fact, we consider that the common small depression at the nasal bridge is best corrected by injection of a small quantity of paraffin wax, and that the result is quite permanent; as to "personal gain," the procedure is simple and naturally commands a much smaller fee than a plastic operation, and it leaves no scar. For resection of the deflected septum Dr. Sheehan describes incision through the columella as "a ready preliminary to separation of the septum from the tissues," but he does not say whether this is his ordinary method of performing a septal resection or, if not, for what cases he would advise it; nor does he state what advantage he finds in a severer method involving an external scar over the usual very satisfactory operation. The operative procedures are sometimes difficult to follow in the text, but the illustrations are sufficient to make them easily understood; these latter are both numerous and good, and the volume is well printed and produced.

### Elementary Hygiene for Nurses.

Third edition. By H. C. Rutherford Darling, M.D., M.S. Lond., F.R.C.S. Eng., Surgeon, Coast Hospital, Sydney, N.S.W. London: J. and A. Churchill. 1926. Pp. 201. 5s.

In its new form this book has been brought so thoroughly up to date that it reveals little of the character of an old work rewritten. It deals in eight chapters with ventilation, warmth, light; food and milk; water, sanitation, and drainage; sewage, dwellings, and temporary hospitals; infectious diseases; parasites; personal hygiene; and health nursing, the last-named section being contributed by Dr. Harvey Sutton. An appendix of 20 pages is packed with facts of practical importance. Written in the Antipodes, this book expresses essentially the English outlook on hygiene, although lack of familiarity with our public health procedure may account for unimportant inaccuracies—for instance, in connexion with the notification of infectious diseases, the grading of milk, and the law relating to preservatives in the latter article of diet. The retention of the term "ptomaine poisoning" is unfortunate, and the paragraphs devoted to food poisoning may give the impression that there is more than a casual association between decomposition and the specific infections involved. The connexion, too, between typhoid and contaminated water is overstressed, and the mnemonics on pp. 239 and 240 might well be omitted. However, the author succeeds in conveying concisely but accurately all that a nurse needs to know of preventive medicine, and the conception of the various branches of the subject, with the exceptions we have noted, is entirely modern. The illustrations are carefully chosen and well reproduced. Altogether an admirable little book which we can confidently recommend to nurses and their teachers.

### Hygiene of Sex.

By Max von Gruber, M.D. Authorised translation into English. London: Baillière, Tindall and Cox; Baltimore: Williams and Wilkins. 1926. Pp. 169. $1.50.

This is a popular exposition of the biology, physiology, and to a very limited extent the pathology of sex. The author has written very directly, and has avoided the errors of taste which such books often exhibit. His style is dogmatic and he finds no place for references to the literature or for the names of physiologists whose experiments are mentioned. This conduces to brevity and simplicity of argument, but has its disadvantages. The statement (p. 82) that injections of serum beneath the skin have been shown experimentally to increase the capacity for muscular activity both by delaying the onset of fatigue and hastening the process of recovery therefrom, is one that we should have been interested to verify in the literature. We take exception to the following statement on masturbation: "Very often by reading him (the child) some of the harrowing descriptions, such as may be found in the medical writings of the past, it is possible to sufficiently frighten him to cause him to break the habit." The inherent dishonesty as well as the exceeding danger of such a procedure calls for protest. We have, however, no serious quarrel with most of the conclusions reached or the advice given.

### Anatomy for Artists.

By E. Wolff. Illustrated by George Charlton. London: H. K. Lewis and Co., Ltd. 1925. Pp. 174. 12s. 6d.

This is a good and readable account of the skeletal and muscular structures of the body as seen from the point of view of the needs of the artist. The descriptions are not tediously long, but appear to be sufficient as well as accurate. Stress is laid on differences between the sexes in anatomical conformation, and a good short chapter on the distribution of fatty masses depending on sexual development is included. We do not remember a similar account in any English book on artistic anatomy, although the subject is evidently one of great importance in the treatment of this subject. The simultaneous action of muscles moving the scapula and the arm, in raising that limb, is mentioned, but we would like to see it more strongly impressed on the student, with a view to the verisimilitude of a reproduction of a limb in action as seen from the back. No mention is made of the action of the rhomboids—a regrettable omission, inasmuch as these muscles are so frequently given actions which they do not possess. The lessened power of extension in the female hip is another matter which might be of import in the portrayal of poses of action. The reference on p. 3 to Fig. 69 should be to Fig. 65. The book is well produced and clearly illustrated with diagrammatic drawings of the muscles and with drawings of the complete parts.

# Reports and Analytical Records.

## (1) TABLETS OF ASPIRIN COMPOUND WITH DOVER'S POWDER (MODIFIED); (2) DIGIFORTIS.

(Parke, Davis and Co., 50–54, Beak-street, London, W. 1.)

(1) This firm for some years supplied tablets according to the formula suggested by Sir G. Archdall Reid in The Lancet of June 4th, 1921, for use in cases of pyrexia and influenza, but as that formula comes within the scope of the Dangerous Drugs Act they have recently introduced tablets of aspirin compound with Dover's powder, modified (C.T. 579), containing rather less Dover's powder, so as to be outside the scope of the Act, and rather more aspirin. Each of the modified tablets contains: aspirin, 6 gr.; phenacetin, 2½ gr.; Dover's powder, 2 gr. The dose is one to two tablets, and the preparation is supplied in bottles of 100, 500, or 1000 tablets. Sir Archdall Reid's original description of his experience with a nearly identical combination in the toxæmia of pneumonia was dramatically instructive.

(2) *Digifortis.*—This is a standardised preparation. While the gravest issues may hang upon the activity of digitalis in the particular form employed, there are few drugs that are more liable to deteriorate. Digifortis is a physiologically standardised digitalis preparation, in the production of which the manufacturers claim to have taken every possible precaution to ensure therapeutic efficiency. The leaves have been specially selected, the fatty constituents eliminated, and the activity of the finished product determined by physiological experiment. Digifortis is supplied in amber-coloured bottles of 1 oz. to protect from the action of light and the deterioration that may follow storage, and a label bears the date of manufacture: the physician will know the age of his stock, and full activity is guaranteed for at least one year from the date. The average dose of digifortis (P., D. & Co.) is 8 minims, two or three times daily, or more often if indicated.

## ISACEN.

(Hoffmann-La Roche Chemical Works, Ltd., 7–8, Idol-lane, London, E.C. 3.)

This is a white powder without taste or odour and is insoluble in water or acids, so that any action it may possess should be exercised in the large intestines. The preparation has been extensively tried out in the Roche Institute of Experimental Therapy at Basle and has been found a useful purgative in cases of constipation of varying origin even in quite small doses.

# New Inventions.

## A NEEDLE FOR SALINE INJECTIONS INTO THE PERITONEAL CAVITY.

For infants the intraperitoneal injection of saline has many advantages over subcutaneous or rectal administration. More fluid can be given; it is more quickly absorbed; there is less discomfort to the child, and glucose solutions up to 10 per cent., and blood, can be used in injections. The objection is that there is some danger of perforating the intestine or of setting up peritonitis, apart from injury to the intestine. These dangers are no doubt present when one-end needles are plunged blindly through the abdominal wall or when the solutions used are not aseptic. In a series of cases at the Evelina Hospital for Sick Children we have had uniform success with a two-end needle, which is used as follows: A fold of skin and abdominal wall (1 in. across) half way between the umbilicus and symphysis pubis is gripped tightly between the thumb and forefinger and the absence of peritoneal contents appreciated. During the period of relaxation which occurs with expiratory apnœa (which periods are long in these infants) a rapid transverse stab is made just below the gripping fingers until the point of the needle emerges from the opposite half of the abdomen, and the needle is adjusted, so that the aperture half way along the curve opens into the peritoneal cavity. That this adjustment is accurate can be appreciated at once by the ready flow of saline, without bulging of the abdominal wall. In these infants the abdominal wall is very lax and an easily safe margin can be raised. Sometimes the injection sets up vomiting, but this can be partially avoided by injecting slowly. The needle has been made for us by J. H. Montague, 69, New Bond-street, London, W. 1.

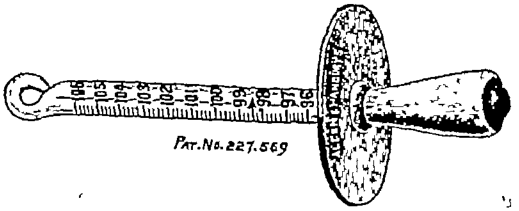
Evelina Hospital for Sick Children, Southwark.

## AN INFANTS' CLINICAL THERMOMETER.

The illustration shows a thermometer which is designed to take an infant's temperature by the mouth. The usual method of taking an infant's temperature by the axilla or by the rectum have their obvious disadvantages. This instrument consists of a special thermometer with a spherical bulb, the lower portion of which projects through a reinforced teat, the end of which is invaginated and protects the neck and upper portion of the bulb of the thermometer. The thermometer of necessity takes a little longer to register than the ordinary clinical variety, as the infant is allowed to suck the teat in the same way as a "dummy," the bulb lying between the tongue and the roof of the mouth.



Messrs. Allen and Hanburys, Limited, are the manufacturers.

G. F. Randall, M.R.C.S., L.R.C.P. Lond.
Sheffield.

THE LANCET.

*LONDON · SATURDAY, MARCH 27, 1926*

## AN ESSAY IN EXPERIMENTAL EPIDEMIOLOGY.

THE problem of epidemiology to-day is to harmonise the facts which may be found in CREIGHTON'S History of Epidemics in Britain or in Sir WILLIAM HAMER'S sheaf of reports on the health of London with those which are summarised in MUIR and RITCHIE'S Bacteriology There are, on the one hand, those to whose way of thinking an epidemic is a thing of itself with an individuality which exists in relationship to past and future epidemics of the same kind and of other kinds. On the other are those who see in an epidemic a response to a parasitic agent conditioned by circumstances of the host and of the parasite. If we believe—as in the present state of knowledge we are bound to believe—that parasites are essential causes of infectious diseases, the two points of view cannot be discrepant, nor can they in the end give discordant answers to the problems with which epidemiology has to deal In so far as the answers may have an appearance of discordance, we may be as sure as we can be of most things that the facts or their interpretation are at fault. Much has been done in recent years towards this harmonisation by the joint advance of bacteriology and mass clinical inquiry We know now, for example, that people may harbour virulent diphtheria bacilli without having diphtheria, and that they may become actively immune to diphtheria without ever having had an attack of the disease, the realisation of the carrier state has shown the line along which we may expect to find the solution of many difficulties. We know that the seasonal prevalence of plague is due to the effects of temperature and humidity upon the rat-flea, and it is into these terms that we can translate the cosmic miasmas of the past. In many other ways observations in the field have improved our knowledge, and it might have progressed faster if the numerical data of the health reports were less neglected as subjects of meditation by medical men

But there are at least as many great questions of epidemiology about which we really know little or nothing that may be expressed in bacteriological terms. What happens when an epidemic slowly emerges, gathers increasing momentum during its climax, culminates, and then falls down to die away back to the level it started from? What are the respective shares of microbic virulence and host resistance in this cycle whose regularity and definite characterisation gave it a personality before parasites were thought of? Is the decline of an epidemic due to a falling off of virulence or to the exhaustion of material susceptible under the conditions of invasion which obtain? Are the hosts which survive at the end alive because they are by nature more than ordinarily resistant, have they become resistant during the epidemic, or have they escaped by chance? The answers to these and other fundamental questions are at present simply unknown, and from the nature of the case are bound to remain uncertain if only the human facts are available Sooner or later medicine always reaches the point where progress is hampered or barred by its respect for human life and comfort, and it is only by resort to experiment on animals that one can get further. This is plainly true of epidemiology, and we welcome most heartily the beginnings which have been made in this country by Prof W W C TOPLEY and at the Rockefeller Institute by Dr L T WEBSTER and his colleagues. We say beginnings, because their study of mouse epidemics, like all really good pieces of work, has not only added substantially to our knowledge, but has made more apparent our ignorance For example, we know nothing whatever about epidemic influenza, and have not a notion why there was a dreadful pestilence in 1918, we have not the least idea why bubonic plague ceased to be endemic in England and Wales in 1666, nor can we tell at all why scarlet fever ceased to be virulent about 25 years ago, although it is still, perhaps, as prevalent as ever Very likely the explanations of all these mysteries are there for us to read, but we do not know the language in which they are written Prof TOPLEY and his co workers are trying to compile a grammar

We publish this week the third and last of Prof. TOPLEY'S Milroy lectures, commending the series to the attentive study of our readers It is necessary for their proper appreciation to realise not that the results of mouse epidemics cannot be transferred without qualification to human epidemics—that is obvious enough—but that this is the only means by which essential information can be obtained Note, for example, the table in the second lecture (p 530) which gives the state of 1160 survivors from various experimental infections as regards the presence of mouse-typhoid bacilli in the spleen, the majority have not escaped infection nor completely recovered from it, but still contain live microbes, and under some circumstances would be capable of starting a fresh outbreak One of these conditions Prof TOPLEY has defined as the addition of fresh normal mice to the population, this will result in further deaths of the survivors from the previous epidemic as well as among the new immigrants—a most curious demonstration We are not attempting to discuss at length the points raised by the mass of work which has been accomplished, we can only emphasise the fact that by it we are for the first time getting definite facts on many points where we have had to be content with surmise and inference, and we hope that the Medical Research Council will continue and expand its support of an admirable enterprise

◆

## SIGNED ARTICLES IN THE PUBLIC PRESS.

THE signature by medical men of articles in the press has been receiving notice for some time, interest being revived regularly whenever there is a cognate discussion in the General Medical Council The matter has been made recently the subject of a pronouncement by the Council and the editorial columns of many daily and weekly papers have had references to it. From these it becomes clear that there is a widespread desire on the part of the public to receive sound medical information through the medium of their newspapers, and the press, designing to meet the demand, has, in certain cases, resented the difficulties which are experienced Editors do not sympathise with the reluctance of medical men to satisfy this demand, or at any rate to satisfy it along what seem to editors the right lines. And this in itself proves that the situation is not a simple one Especially the reasons are not
which have led the General Medical Co
circumstances, to hold the writing of
in the press as "infamous conduct

respect"; yet it is a fact that on the comparatively few occasions when practitioners have incurred the censure of the Council for the insertion of such articles the logical attitude of the Council cannot be challenged, or only in a tentative manner. No medical man has been "molested"—to use a word frequently employed—by the Council, when he was giving sound medical advice or information, neither intruding his own personality nor dogmatising on disputed pathology; the penalty has always been incurred through the injudicious or self-advertising nature of the communications, resulting in possible deception of the public. The memorandum now issued by the General Medical Council, through the Registrar, states definitely that the publication in the press of articles on medical subjects by practitioners has not been condemned by the Council, unless it has been proved that the articles come under the terms of the warning notice of the Council against advertising, or are otherwise of an objectionable nature. The responsibility rests with the Council to decide whether any articles signed by a medical man in the press do constitute advertising or are objectionable; and when a practitioner, with due formality, is asked to explain his conduct, the issues are heard in public (though not the deliberations of the Council upon them), the impeached man being present, and, if he chooses, being represented by counsel or solicitors. A judicial assessor assists the Council in regard to any points of law and indicates the legal weight of the evidence, so that all precaution is taken against hasty or improper action. Some critics of the Council have certainly not been aware of the safeguards possessed by the practitioner.

The attitude of the British Medical Association was made public at the Representative Meeting last year, when the policy of the Association in reference to the contribution of articles on medical matters to the press was formulated in a clear report. This report held that it was legitimate, or even advisable for medical practitioners, who could speak with authority on the question at issue, to contribute to discussions in the public press, but stated that discussions on disputed points of pathology or treatment should be avoided. The matter would be simple if it were possible for the medical article to be at once devoid of reference to pathology, unconcerned with treatment, and at the same time to be the sort of article which the public press seeks, because it is what their readers desire to have placed before them. And this is one reason why the situation, as we said above, is not a simple one. The articles which medical men are begged to supply to the press almost always deal with pathology or with treatment or both. So that the points to be discussed, if the real ethical difficulties are to be faced, are not provided for either in the expressed opinion of the Representative Body of the British Medical Association or in the memorandum of the General Medical Council. The Council could not possibly pronounce all articles in the press which had pathological or therapeutical references to be indications of ethical laxity; and the British Medical Association could not possibly say that because an article was silent on pathology and therapeutics it contained no element of professional offence. The General Medical Council is concerned with preventing the appearance of articles of a self-advertising or objectionable nature, and the articles which will lead directly to penal interference are those where the self-advertising takes the form of giving advice on disputed pathological questions from an assumed superiority of knowledge. Many articles which are not objectionable, in that they do not mislead the public scientifically, may bring their authors before the public in a manner that their colleagues think unfortunate; they may acquit the author of self-advertisement but still consider that he has secured a measure of publicity in an undesirable way through his action in writing the articles. This is why a practitioner whose name comes before the public through the announcement of simple hygienic lessons is accused of self-advertisement; he does not offend by pretending in so many words to superior individual knowledge, but the signing of the article confers that quality upon him, and it is the quality which the journal issuing his contribution would suggest that he possesses. He is really doing good, but the inconvenience of his conduct is that, when another man does the same thing and in the other man's article direct advertisement can be detected, so that his name is removed from the official list of the profession, the public considers that an unfair difference of treatment has been meted out by the General Medical Council.

The practitioner who desires to sign an article in the press should feel sure that what he has to say needs saying, that he has the right experience from which to say it, and that he is not introducing to an audience, unable to doubt, from technical knowledge, the theories, deductions, or opinions which he could not support among his colleagues. It is an act of vanity, which may have mischievous consequences, to promulgate personal views where they are unnecessary and where they cannot be challenged. The practitioner who accepts an invitation to contribute a medical article to the press, having similar considerations before him, should feel sure that the public will gain by the information which he has to give, and that it has been sought from him because he is admitted by his colleagues to be an authority. And thereafter he should remember that, if he gains in public esteem he may none the less be held to have broken the spirit though not the letter of medical ethics. This is a consequence following either upon the right or the wrong conduct; and the fact that it may occur in either case shows again that the situation is not simple.

## MEASLES.

FOR the third week running more than 100 deaths from measles have been reported in the 105 great towns of England and Wales. In years when measles is prevalent this high mortality is not unusual. But is it still inevitable? Is it impossible to save these lives? Or are they lost because the fullest use is not made of modern knowledge of the disease—because a certain fatalism or indifference still governs medical opinion? That measles may have disastrous results is fully recognised; its complications and sequelæ are known to everyone. Yet the fact that in good surroundings it is rarely fatal gives a semblance of reason to the opinion that it is a trivial complaint; and it is thought of with the less concern because infection seems inevitable. Few escape it in the long run, and since one attack almost always confers lasting immunity, people think that a child may as well get it over. That, however, depends on circumstances. Certainly there is little enough harm in allowing children to take the disease in well-appointed, airy homes, where they can be properly looked after, and where there are no foreign bacteria to take advantage of the chances offered by inflamed nose and throat and bronchi. Here measles is rightly regarded as of little account. But in the overcrowded houses of the poor it assumes a different and deadly character; and accommodation in fever hospitals cannot, as a rule, be provided until some complication occurs, when it is often too late. In schools, hospitals, and other institutions an outbreak of measles is wholly undesirable, because it reduces the sufferer's resistance to the organisms carried about by his companions, against which he has not acquired effective immunity. Thus an overlooked middle ear infection may be lighted up, risking the spread of otitis through a school; whilst diphtheria or some other fever supervening on an epidemic of measles may be a calamity. It makes a difference, moreover, at what age the child catches the infection. In the outbreak at Camp Wheeler in the U.S.A. in 1917 it was found that all the recruits, sooner or later, took measles unless they had had it before, and it seems that effective inborn immunity is rare, if indeed it occurs at all. The exception is the new-born infant who is said not to catch measles even from the mother nursing him—a fact of great theoretical interest. Apart from this, age has little bearing on susceptibility, but it has an important influence on mortality and the danger grows less as the age approaches 5 years. For this reason it is useful to prevent measles in young children even if the prevention is only temporary, and for the reasons stated above it is most desirable that this usually minor complaint should never be allowed to take its course in schools, institutions, or unhealthy homes.

That is almost axiomatic. But is there any way of preventing people from catching measles, apart from quarantine? The answer is that there are methods used abroad which ought to be tried more widely in this country and which, on the evidence, may be assumed effective until proved otherwise. For the moment it will be convenient to leave on one side the interesting attempts of Morey to produce active immunity by painting the throats of new-born infants with nasal discharge from measles patients, and consider only the uses of serum, which has been repeatedly described in our columns.[1] Serum from a convalescent case of measles was first tried in 1916 to protect susceptible children. Since 1919 it has been used in many continental cities and in North and South America. Degkwitz, of Munich, has worked out the doses needed to confer immunity, and considers that on entering a house where there is a case of measles the doctor should immunise the contacts with convalescent serum. Supposing that the rash has but just appeared, a dose of 3 c.cm. will give complete protection to the other children. If the disease has been developed for 24–48 hours some 5 or 6 c.cm. will be required; whilst if the time since exposure to infection is more than three days, larger doses will be needed and protection is less certain. Early injection of serum only confers a passive immunity, which lasts but a few weeks. (Not that this would not be extremely useful in certain circumstances, as for instance, in school outbreaks.) But where injection is not made until five to seven days after exposure a modified and mild attack results, which is said to give lasting protection. If the exact date of exposure to infection is known it may therefore be worth while to delay the injection and get an attenuated attack so that the child may be protected against further accidental exposure, which is almost certain to occur sometime or other. If the claims of Degkwitz, Debré, and others are justified, it is clear that we may possess an effective method of controlling measles. We have a means of preventing serious outbreaks in schools and hospitals, of mitigating the severity of attacks in cases seen up to seven days after exposure to infection, and of conferring permanent or temporary immunity according to the exigencies of the occasion. The careful and considered use of such a method may well rob the disease of its worst perils. In Paris, New York, and elsewhere centres have been arranged for the collection and testing of serum to ensure freedom from syphilis, tuberculosis, and malaria. Where the serum of convalescents is unobtainable the serum or whole blood of an adult who has suffered from measles in childhood may be used instead, but a larger dose is needed—e.g., 12 c.cm. serum or 35 c.cm. whole blood for a child of 3 years—and this is only recommended for country districts where no stock serum is available.

Dr. R. Veitch Clark, medical officer of health for Manchester, is reported to have said that the country could easily be rid of measles if the public would coöperate and overcome its prejudice against injection. It would be something, however, if we could say of measles, as Sir George Newman recently said of small-pox, that only those had it who preferred it. The suggestion that to eliminate measles may be feasible has raised other interesting, if academic, questions: Would such elimination be wise? Would not a nation freed for a generation fall an easy prey to infection brought in from abroad? When such infection came would it not play havoc with a population which had lost its power of resistance? For 65 years the inhabitants of the Faröe Islands were free from measles, and when, in 1846, it was reintroduced, over 6000 of the 7782 islanders contracted the disease and many died. Even more striking was the epidemic in Fiji in 1875. Measles had been unknown in the islands and presumably the people had no specific resistance whatever. Amongst the population of 150,000 there were about 40,000 fatal cases. This fact, at first sight, lends colour to the view that it is better to keep the measles we have than loose a plague like this upon our descendants; but Corney, who observed the epidemic, considered that it would be easy to lay too much stress on the absence of inherited resistance in the natives. He put the mortality down mainly to lack of care for the sick, to the bad habits of the people (who treated their fever by lying in rivers for hours at a time), to starvation due to the whole population being stricken at once, and to want of cleanliness. The disaster was mainly caused, he considered, by factors which would not operate in a civilised community. Attempts to stamp out measles in this country need not, we think, be hindered by any fear of massive reinvasion. Complete eradication is hardly practical politics at present, but even if at some distant date the population were rid of measles for a generation, there is little reason to think that they would become remarkably susceptible to reinfection. Any situation that arose could presumably be controlled by a health service using the means which had originally banished the disease, and there seems no reason for panic about the plight of our grandchildren.

◆

## HEALTH ADMINISTRATION IN WALES.

The death of Sir David Evans at Cardiff on March 18th recalls an interesting, and in many ways successful, experiment in national health administration, for in 1918 he was appointed director and legal advisor of the King Edward VII. National Memorial Association, which undertook responsibility for the treatment of tuberculosis throughout the whole of Wales. Under his guidance the Principality was able to provide rapidly and economically institutional accommodation on a scale unapproached by any except a few of the very large sanitary authorities in Britain. The scheme has now been in existence for 10 years and has not escaped criticism, directed chiefly to its effect in removing tuberculosis from the purview of the local health departments. The problem of tuberculosis, as may be seen from the history of its decline before ad hoc schemes came into being, is not merely one of treatment and specific prevention. Even in this respect the vague impression that the local health department has no official concern with tuberculosis is rejected in the negligence among practitioners in Wales of that notification of the disease on which its early treatment depends. Still more detrimental, however, has been the removal of the stimulating effect which tuberculosis might have exercised on the interest of contracting local authorities in the problems of housing and poverty in relation to health. However distinguished and able the medical staff of the Association, it is clear that their contact with other health activities must be precarious and occasional. From the purely medical point of view it is difficult to assess the results of the scheme. It appears to be the case that the mortality from tuberculosis in the rural areas of Wales is declining more rapidly than in the whole of England, but this is probably associated with the greater distance it had to fall. On the other hand, the annual reports of the medical officer of health for Cardiff contain repeated references to the high tuberculosis death-rate and the unique position of that town in having a slower rate of decline in the tuberculosis than in the general death-rate. The Consultative Council of the Welsh Board of Health is now proposing a radical change in the medical services of the Principality as a whole, which would in effect bring them into line with the National Memorial by the creation of a National Health Council for Wales. We are not sure that the disadvantages of any such scheme might not outweigh its benefits, for it would interpose between the Welsh Board of Health and the local authorities a new body either having little more executive function than the Board itself, or else exercising such powers over an unworkable area. Wales and Monmouthshire together cover more than five million acres and many localities in this area are difficult of access. Only one county in England approaches Wales in acreage, and it has been found convenient to split up this county—Yorkshire—into three parts for efficient administration. In any attempt to measure the influence of local methods of administration on health statistics, it is important to remember that the large urban districts of the Southern half of the Principality differ in only one material respect from the bulk of similar areas in England—namely, their almost entire dependence on the coal industry. Even in this respect Wales has its counterpart in some English areas, notably in the County of Durham. All such urban districts constitute a grave public health problem, and their effect on the mortality returns is reflected in the statistics published by the Registrar-General both for Wales and the Northern Counties. Even the rural districts of both Wales and the North of England figure badly in these statistics, but here again it should be remembered that the rural districts of Glamorgan and some of the Northern Counties, which weigh so heavily the statistical returns, are much more industrial in character than those of the Midlands and the South of England. Group comparisons are apt to be fallacious. Nevertheless it is a fact that the purely rural parts of Wales, as distinct from the populous so-called rural districts, are unfortunately placed in respect of maternal mortality and pulmonary tuberculosis, and that many, even of the counties in North and Mid-Wales, are themselves too sparsely populated and too poor to form effective public health units. But it may be taken for granted that any scheme which aims at diminishing the heavy maternal mortality in the rural districts must be largely a local scheme, and will gain little or nothing from central administration. The one sound argument for enlargement of the areas of health administration is financial. Few of the rural areas either in England, Wales, or Scotland would be able to face the expenditure on medical services which transfer of the functions of the Poor-law authorities will ultimately involve. No doubt it is partly for this reason that the Minister of Health is suggesting the councils of counties and county boroughs as the new authorities. Some of the Welsh counties may be too small to be efficient units, but public health and allied legislation already enables combination of authorities for specific purposes. Development of the policy of joint action would permit of reasonable enlargement of areas to meet financial difficulties without losing that homogeneity of interest which is so apt to be lost in national schemes. We commend the Consultative Council's proposal to the critical attention of all who are interested in the wider aspects of public health.

---

# Annotations.

"Ne quid nimis."

## INFECTIVE ENDOCARDITIS.

The subject of infective endocarditis which Sir Thomas Horder has chosen for the Lumleian lectures is of special interest to the practitioner, for it is one of a group of subacute infections which have become a conspicuous feature of the medicine of the last 15 years. A great deal has recently been written, both from the clinical and the laboratory point of view, on infective endocarditis. The general trend of opinion nowadays is to recognise two main varieties of infective cardiac disease, the pericarditis of rheumatic origin and the endocarditis of bacterial origin. Dr. Carey Coombs expressed this view very clearly in the Long Fox Memorial Lecture delivered at Bristol on Dec. 9th, 1925, when he said "the heart of rheumatic infection is attacked in all its parts at once, obviously through the coronary vessels and their ramifications, while in ulcerative endocarditis the lesion is primarily and mainly one of the inner lining of the heart, the myocardium being injured only occasionally, either by direct extension therefrom or by embolism, while the pericardium never suffers." These different pathological lesions in the two types of infection have been commented on also by Prof. W. S. Thayer in his voluminous report entitled "Studies in Bacterial (Infective) Endocarditis," published as one of the Johns Hopkins Hospital Reports (vol. xxii., fasc. 1). He studied clinically and anatomically 198 cases of bacterial endocarditis occurring in the Johns Hopkins Hospital for the past 34 years. For the sake of comparison he analysed also 24 cases of uncomplicated, fatal, acute and subacute rheumatic heart disease. One of the chief interests of this research is in the comparison of the clinical course and pathological lesions in the different varieties of bacterial endocarditis. These facts are set out in great detail in this report. The ætiological element in this series of cases of bacterial endocarditis turned out to be in 55·5 per cent. of cases the streptococcus, pneumococcus in 13·6 per cent., *Staphylococcus aureus* in 12·1 per cent., gonococcus in 11·6 per cent., *B. influenzæ* in 4 per cent., while *Staphylococcus albus*, *B. pyocyaneus*, and *B. anthracis* were represented only very rarely. The commonest type of lesion caused by these bacteria was a verrucous, vegetative, or ulcerative, valvular or mural endocarditis, associated sometimes with acute, often suppurative, pericarditis and focal, sometimes suppurative, myocarditis.

On the clinical side Prof. Thayer distinguishes two main forms of bacterial infective endocarditis. In the first the lesions appear commonly as complications or sequels of some focal inflammatory process with an accompanying septicæmia, which is usually rapidly fatal. Under such circumstances the existence of cardiac disease is generally masked by the symptoms of the acute infection of which it is a complication. In the less acute cases which run a course of several weeks the changes are usually vegetative or ulcerative. In most acute septicæmias the cardiac disease is clinically a mere incident in the course of the primary infection. The second main form of bacterial disease of the heart is that associated with infections with attenuated streptococci, notably *Streptococcus viridans* and with *B. influenzæ*, the distinguishing feature of this disease being that the endocardial focus is truly the main seat of the disease. The course of the malady is slow, subacute or chronic, lasting over weeks and months. The onset is insidious; the portal of entry obscure; the areas involved are generally the seat of previous chronic rheumatic disease. The manifestations are rather those of subacute or chronic septicæmia to which later the characteristic embolic phenomena are added. Here the subacute endocarditis is in itself the essential pathological entity. In contrast to these two varieties of bacterial heart disease we have the rheumatic type of heart disease on which Prof. Thayer cautiously remarks that "the positive proof that a definite specific strain of streptococcus may be regarded as the causal agent of rheumatic fever can hardly be said to have been afforded." Rheumatic fever and chorea stand together as manifestations of that infection which is associated with the peculiar acute cardiac changes which we class as "rheumatic." Here the lesions affect the entire heart and consist of the perivascular Aschoff bodies, the frequent serofibrinous pericarditis, the slowly developing and cicatrising valvulitis and verrucous endocarditis, notably of the mitral orifice. These processes terminate in the familiar picture of chronic valvular disease of the heart with disseminated perivascular fibrosis of the heart muscle and often with adherent pericardium.

Prof. Thayer is unable to throw much new light on the question of treatment of infective cardiac disease. He finds little encouragement can be gathered from our therapeutical experiences. Apart from rest and proper nursing he has little to recommend. It is disappointing that specific treatment has been so unsatisfactory even in those cases where the causative microbe was accurately identified and facilities were available for specific vaccine and serum treatment. Prof. Thayer observes that in subacute infective endocarditis the patient rarely escapes meddlesome treatment. "The anxious family, showered with well meaning advice from many quarters, is for ever urging the doctor to try some new and often absurd method of treatment, and the unfortunate patient, whose main chance lies in peace of mind and body, is surrounded by an atmosphere of perpetual turmoil, and, if he be well-to-do, is often subjected to a succession of consultations which alarm and tire him and lessen the few chances of recovery that are his."

## SPECIAL HOSPITALS AND CHRONIC DISEASE.

WE have received from Dr. Berthold Beer, of Vienna, an interesting letter enclosing two articles written by him to Viennese papers, his letter being prompted by reading the reports of the recent references in the House of Commons to the problems of unqualified practice. Dr. Beer has been well known for a long period to many in this country as keenly interested in these problems, and he gives it as his opinion, founded on experience in Vienna, that attempts at diminishing unqualified practice by legislative measures are doomed to failure. Here the experience in Austria is exactly what those in this country who have studied the subject most closely would have expected. He believes that one of the most effective measures against the prevalence of unqualified practice would be to secure improvement in dealing with prolonged and chronic cases by means of special hospitals for such cases, and this is a good point, for it is from chronic cases that the amplest harvest of the irregular practitioner is reaped. If there are greater opportunities for medical practitioners and medical students to learn how to help cases of chronic crippling disease, there will be less reason for the public to resort to those the value of whose services has never been tested. This idea was propounded many years ago by Prof. v. Ziemssen, of Munich, and undoubtedly considerable advances follow in the treatment at central clinics for the purpose of chronic diseases like scleroderma, contractures, keloid, and adherent scars following burns. Dr. Beer believes that relief would be obtained after more intensive study for various conditions of deformity of the joints as well as for the disabilities termed "rheumatoid arthritis"; and he points in support of this view to the amount of benefit which can be given to cases of old paralysis and muscular atrophies after lesions of the nervous system by appropriate mechanotherapy. In an article published in the *Illustriertes Wiener Extrablatt* of Feb. 11th, 1926, he develops this idea in an interesting and instructive manner, and in emphasising the special importance of the subject in all the countries which took part in the recent great war, he finds Germany in particular to have recognised the matter as one of national need, though he refers to successful efforts under a method of treatment introduced in Vienna during the progress of war and generally known as the Vienna Manual Method. In a sequel to this article, he points out how, in the Vienna Manual Method, women can be trained under medical supervision to give special mechanical modes of treatment with great benefit to such patients.

In all large communities, whatever the nationality, there must exist this sound reason for the development of special hospitals for the treatment of chronic disease—namely, that in the general hospitals chronic cases cannot be sheltered owing to the pressure on the beds. We all know too well that these cases are often discharged with the stigma of incurability when, under more prolonged and more specially devised treatment, they might have been restored to some degree of working capacity. Dr. Beer's epigram, "the chronically ill require chronic treatment," says the last word if any want convincing.

## LOUVAIN LIBRARY.

IN a recent *Bulletin* of the John Rylands Library Dr. Henry Guppy, D.Ph., librarian of the John Rylands Library, describes the reconstruction of the library of the University of Louvain, detailing the contributions of this country to the work. The destruction of the famous library of the University of Louvain was one of the earliest shocks to the culture of the world following on the outbreak of war; it brought to the public conscience a knowledge of how the civilisation of the future might be jeopardised by the wrecking of the past. The arousal of this feeling led to a scheme for the reconstruction of the library, inaugurated by the governors of the John Rylands Library in the first year of the war. Publicity to that scheme was given immediately in these columns, and those of our readers who contributed to the happy result will be glad to learn that the University of Louvain, through the British Committee, has obtained 55,782 volumes, forming a live collection of books to replace, as far as possible, the grand library so miserably destroyed. The twelfth consignment of books, probably the last that will be sent, was despatched in July of last year, and consisted of 68 cases containing 6071 volumes, including the splendid collection of oriental and general literature bequeathed to his alma mater by the late Bishop of Salford, Dr. Louis Charles Casartelli. In the report Dr. Guppy points out that, although definite action had sometimes to be postponed, British Universities, learned societies, and libraries had signified their desire to refurnish the Louvain Library at the time that the appeal was made by the John Rylands Library, while America's part in providing a million dollars for reconstruction, and a further donation of 125,000 dollars with which to create a trust for upkeep, is recorded with gratitude. The first stone of the new building was laid on July 28th, 1921, in the highest part of the town overlooking the Palace du Peuple, the exact spot where a little Belgian force defied the German army. No attempt will be made to reproduce the destroyed building, but every detail of the new design is Flemish, and brick and stone of local origin will be used in its construction. In the completed building there will be accommodation for two million volumes, but the English gift will be kept apart both on the shelves and in the catalogue. Thus, the attempt will be clear "to acknowledge our indebtedness to the incomparably brave nation and their valiant Sovereign, who sacrificed all but honour to preserve their independence and thereby safeguard the liberties of Europe." Although the destruction of the Louvain Library has resulted in an irreparable loss to literary history and associations, there is a brighter side to the situation, and this finds expression in Dr. Guppy's report. A university library is, in a sense, a symbol of education, and education has in modern times been completely revolutionised. Many of the books which have now found their way to Louvain, replacing works of interest through antiquity and historical association, might otherwise never have reached the Belgian University. The reorganisation of the Louvain Library, especially in the domain of investigation and research, is an admirable event for education.

## TUBERCULOSIS IN MENTAL HOSPITALS.

In a paper read recently before the Tuberculosis Society Dr. E. A. Evans, inspector of the Board of Control, drew attention to the high incidence of tuberculosis in mental hospitals. Apart from Poor-law institutions, naval and military hospitals, and the criminal lunatic asylum, with none of which, said Dr. Evans, was he concerned that evening, the daily average number of patients resident each year between 1910 and 1925 ranged between 87,000 and 106,000. The tuberculosis death-rate per 1000 living had varied among these patients from 13·8 in 1910 up to 45·6 in 1918, and down to 7·3 in 1925, the corresponding death-rate for England and Wales in 1920, for ages over 15 years, being 1·3. Since mental hospitals differ widely in size and in type of management the death-rate from tuberculosis is found, as might be expected, to vary with the type of institution—e.g., a much smaller death-rate from this disease is found in the establishments for private patients, and a similar disproportion is believed to exist in the private annexes to rate-aided institutions. In comparing the tuberculosis death-rate in mental hospitals with that for the general population several sources of fallacy must be borne in mind. For instance, as regards age distribution, in the general population about 27·4 per cent. are under 15, while in the mental hospitals the percentage for this age-group is about 0·6; indeed, nearly 50 per cent. of the population in mental hospitals are over 45. Again, one might reasonably expect that with this high proportion of aged persons in mental hospitals the number of deaths from respiratory diseases other than tuberculosis would in these institutions exceed that for England and Wales, but as a matter of fact the percentage is 7·7 for the mental hospitals and 20·2 for England and Wales. This discrepancy is accounted for by Dr. Evans by the greatly preponderating percentage of post-mortem examinations carried out in mental hospitals. It is significant that in county and borough mental hospitals in which the percentage of post-mortem examinations carried out is 65·5 the tuberculosis death-rate is 11·2 per 1000, while in registered mental hospitals with a post-mortem examination percentage of 12·6 the tuberculosis death-rate is only 4·4 per 1000. The very definite correlation between infrequent post-mortem examinations and low tuberculosis death-rate would suggest, as Dr. Evans pointed out, that extended autopsies might reveal more deaths from tuberculosis among the aged at the expense of the diagnosis of chronic bronchitis.

Dietary defect had, said Dr. Evans, been widely blamed for this high mortality in mental hospitals. For the purposes of a research carried out in 1922 hospitals were grouped in three classes: (1) those with dietaries of less than 2300 calories; (2) those between 2300 and 2600 calories; and (3) those over 2600. With each rise in caloric value a correspondingly lower incidence of tuberculosis was found and, in the case of males (but not of females), a similar drop in the death-rate. Adequate precautions are taken to ensure that no infected meat is used in mental hospitals, but Dr. Evans regards the milk service as less secure, although an increasing number of hospital authorities insist on periodic guinea-pig inoculations with centrifugalised milk from every animal of the supplying herd. Recent substantial improvements in the dietaries have been reflected in the falling incidence and death-rate of tuberculosis. Another factor investigated has been the effect of the size of the hospitals. As a general rule the larger the hospital the higher is the death-rate from tuberculosis owing, no doubt, to the congregation of large numbers of persons in common rooms and dormitories. For long the safety of the patients was considered to preclude the free opening of windows, a dislike for prison-like architecture also preventing the use of iron bars which would have allowed their wider opening. Greater risks are now taken, and in many hospitals a wire frame is fixed outside the window, while window blocks are being removed from the upper sashes of ground floor rooms.

The prevalence of tuberculosis varies among the clinical types of mental disease. Dr. Evans finds a distinct preponderance among the congenital cases, especially those with epilepsy, and among the dementia præcox or primary dementia patients. In the former group the tuberculous disease runs a chronic course, the patients dying only after long residence. Tuberculous patients suffering from melancholia or dementia præcox, on the other hand, usually die within four years. Dr. Evans believes that there is a definite impairment of metabolism due to, or associated with, the impaired mental condition. It is usually necessary to depend upon the personal observation of the medical and nursing staff for the first signs of illness among the insane, otherwise patients may be found well advanced in serious illness before any complaint is made. At present there is an average of about a dozen patients with active pulmonary tuberculosis in each of the county and borough mental hospitals. In about three-fourths of the hospitals special provision, in the shape of verandahs, open-air shelters, isolation blocks, or special wards, is available for the segregation of these patients.

## THE HAND OF MR. F. T. PAUL.

At the conclusion of the clinical meeting of the Liverpool Medical Institution on March 11th, Mr. J. C. M. Given presiding, the members assembled in the lecture theatre to witness an interesting little ceremony—namely, the presentation to the Institution of a bronze cast of the right hand of Mr. F. T. Paul, executed from a cast by Mr. H. Tyson Smith. Mr. Frank Jeans, the donor of the bronze, said that Mr. Paul's name was known to every surgeon as a pioneer and an inventor, "Paul's tube" being as epoch-making an instrument as that of another Liverpool surgeon, "Thomas's splint." Therefore he thought that, as a remembrance of Paul, a past president of the Liverpool Medical Institution and a most gifted operator, a cast of his hand would be acceptable to the Institution. "Paul's operating in the heyday of his manual efficiency," he said, "always made me think that he did with his hands what Pavlova did with her feet, only Paul's work was much more useful. I have an additional reason for wishing to pay a tribute to Paul, because it is to him that I owe the continued existence upon this earth of my wife—but that is a personal matter." Mr. Paul, in acknowledging the courtesy of the Institution in accepting the gift and the kindness of Mr. Jeans in thinking of it, admitted that at first he had regarded the matter somewhat as a joke, and, while confessing that he had always been fond of using his hands from his earliest years, he reminded the audience that "a gentle touch comes from the heart rather than from the hands, a touch inspired by a true sympathy with the patient's tissue—in this way only could a man attain the hand of a surgeon." The President then expressed his pleasure in accepting the bronze cast in the name of the Liverpool Medical Institution, and thanked Mr. Jeans most sincerely for his very acceptable gift. All our readers will acknowledge the fitness of the retention in the Liverpool Medical Institution of a permanent memorial of the work of Mr. Paul. Not only is he a great as well as a skilful surgeon, but he was one of the founders of the Liverpool Medical School, and from its earliest days his work has contributed to the building up of the great tradition of that school.

## THE NEEDS OF UNIVERSITY COLLEGE HOSPITAL.

DEVELOPMENT has its embarrassing side for those who have to find money for the upkeep of their great possessions. University College Hospital offers a case in point, and clearly its income must increase to meet expenditure if the hospital is to make the most of its new good fortune. The Rockefeller Foundation's grant of £1,205,000 for the erection of more buildings and the equipment of research does not affect the ordinary income except in so far as it will make for economical working, and, unfortunately, the annual deficit remained at about £11,000 last year. Doubtless many subscriptions have been diverted into the fund for endowing 60 beds in the new maternity block which the Prince of Wales is to open on May 28th; £180,000 has been collected for this purpose. The expenses of this collection, it is satisfactory to note, were very small indeed, and the interest earned on the earlier contributions more than covered the whole cost. "We did not advertise for money," says Sir Ernest Hatch, the chairman, "we went and fetched it." Besides these maternity wards, now so well provided for, there is a new nurses' home and medical officers' quarters in Huntley-street, which is already complete, and the Royal Ear Hospital, which is to be ready for use very soon, thanks largely to a gift of £65,000 from Mr. Geoffrey Duveen, a member of the committee. The hospital's existing accommodation had become more and more inadequate, but all these extensions will furnish 203 additional beds. Most of them have been furnished indirectly out of the American grant, but the Rockefeller Foundation rightly considers it no part of its work to care for the sick poor, except by research and medical education. London, therefore, must see to it that the fullest use can be made of what has been provided, and there will be a ready response to the quiet and inexpensive appeal which is being launched. Another £15,000 a year is needed to bring the ordinary income up to a more satisfactory level, and the fact that a great future is obviously in store for the hospital should ensure that this sum is found.

## CHEWING-GUM AFTER TONSILLECTOMY.

IN a recent number of the *Therapeutic Gazette* (Feb. 15th, 1926), Dr. William H. Spencer, of Philadelphia, draws a somewhat lurid picture of the septic condition of the throat after tonsillectomy, and of the systemic absorption of toxins from the "putrefying mass" which covers the wounds. He is scornful on the subject of gargles, though he does not mention the probability that they do not reach the tonsillar fossæ at all, and it would seem that he has no experience of spraying or syringing the throat in this condition. But he is an enthusiastic advocate of the use of chewing-gum after operation, and states that "the throats of tonsillectomised individuals using chewing-gum as an after-treatment do not become infected. Secondary hæmorrhage is less frequent." (It is very rare in any case.) "Healing is more rapid. A full diet being taken, resistance of the individual is maintained, little or no weight is lost, and no post-tonsillectomy recuperation period is needed." "Chewing stimulates the secretion of saliva, which, being swallowed, laves constantly the wounded surfaces and lubricates the pharyngeal mucosa. The attrition of swallowing keeps down the membrane formation to a minimum, so that the usual white patches covering the tonsillar fossæ, which have often been mistaken for diphtheric membranes, are in some cases entirely absent." Patients might not take so kindly to this method here as in a country where they are already used to it; in the United States, according to Dr. Spencer, "so universal is the habit that it can be chewed in public without attracting the slightest attention." Nevertheless, surgeons here who are not satisfied with their patients' convalescence under the usual methods, may like to try this form of after-treatment, which is, at any rate, simple and harmless.

## LONDON UNIVERSITY.

THE long expected report[1] of the Departmental Committee of the University of London appears by a curious coincidence a few days before the surrender of the promised Bloomsbury site. For it seems certain that next week the conditional offer of this site to the University for its central buildings will lapse definitely and its value be claimed by the Chancellor of the Exchequer. The event might have passed unnoticed had it not been for a demonstration of students who last week beat the bounds of what was to have been their home on the same day as a petition signed by over 4400 students and teachers was handed to the Prime Minister, asking the Government that all should not be surrendered and that part of the site should be reserved for residential quarters and a students' Union. Even if no promise has actually been broken, the students may be right in claiming that the engagement ring should not be returned; and they may take comfort fom the words of the Departmental Committee, which states that, wherever the central offices of the University are to be located, the creation of a strong University Union is eminently desirable and is a proper charge on the funds of the University. The report of the Departmental Committee differs from the Final Report of the Royal Commission of 1910, issued in 1913, and of the Haldane Commission of 1900, in being a readable document of 52 pages with 5 pages summarising its recommendations. The report makes no attempt to present a record of the development of the University, nor to discuss in detail its aims or constitution. The Committee frankly regards it as impracticable to give effect to some of the major recommendations of the Haldane Commission. It has been concerned to devise an immediately practicable scheme for better government and organisation, evolutionary rather than revolutionary, and yet embodying the essentials of a university in a great centre of population. The fear raised by the Haldane Report of an attack on the system of degree examinations for external students is found to be groundless. In the evidence laid before the Committee no responsible body claimed the abolition of these degrees and none of the Committee's recommendations is designed to restrict the present facilities available for external students. The Committee refuses to emphasise the distinction between external and internal sides of the work of the University, provided that the authority of the teachers and of the teaching institutions on the academic side is safeguarded. As time goes on it assumes that internal graduate members will gradually outnumber the external graduate members, so that the organisation of the external side will become increasingly dependent upon the support of internal graduates. The Committee recommends no further extension of incorporation which is now not regarded as an effective instrument for securing financial and educational control. It has been influenced largely by the difficulties which have had to be surmounted in the case of the medical schools and of the Imperial College at South Kensington. No plan of separating the schools from their parent hospitals or of selecting from among the 12 general medical schools three which should qualify for incorporation has been evolved satisfactorily. Nevertheless, in the meantime the closer inter-relation of these schools, along with the aid of the University Grants Committee, has enabled six of them to organise units and to qualify for University chairs in clinical subjects. Some of the advantages to be hoped for from incorporation have thus been achieved without it. But the system of direct Government grants from the Treasury to unincorporated schools is condemned by the Committee, which regards such a course as indefensible and inconsistent with any form of University government; and one of its main proposals is to set up a University Council to determine the allocation of funds for the execution of University policy. The proposed constitution of this Council and of a reorganised Senate and of the five standing committees of the Senate are set out clearly in the summary of recommendations. No one who reads the report can fail to appreciate the spirit in which the Committee, under the chairmanship of Mr. E. Hilton Young, which included in its number Dr. H. L. Eason, has done its work, and all those who feel strongly the dangers of interfering with the delicate works of a going concern may breathe more freely.

## CONGENITAL DEFECT OF ARMS.

THE wonderful results which may be achieved with very small means are in no cases more striking than in those of congenital defect of the limbs. In the case of the lower extremity, persons suffering from defect of the legs have ridden on horseback across country, and of this A. M. Kavanagh, the well-known sportsman and politician, who had neither hands nor feet, was a striking example. Numerous cases of congenital defect, or very early loss of the upper limbs, are on record in which the sufferers have made their feet do duty for hands with an astonishing degree of success. The celebrated Miss Biffen earned a niche in the temple of fame of the Dictionary of National Biography, and there have been painters on the continent who defied the disadvantages of their birth and achieved a large measure of technical success. Only two years ago a young man named Elroy, whose arms had both been amputated at the shoulder-joints in infancy, exhibited the wonderful adaptation of his feet, with which he achieved various difficult tasks, as well as performing nearly all the offices of daily life for which the hands are normally used. He used no artificial help, yet he possessed no muscle and carried out no coördinated movements of which the normal infant does not possess the potentiality. In cases of congenital defect of the arm it is generally found that, however small the rudiments of the upper extremity may be, its owner can do more with the bare stump or stumps than he could do with the most ingenious and well-fitting prosthesis. Hitherto surgery has been able to do little for such cases which it has seemed best to leave to their own wits and persevering energy and to the education of experience.

Recently, however, Dr. Harry E. Mock, of Chicago, has reported in the *Journal of the American Medical Association* (Feb. 20th, 1926) a case of congenital defect of both arms and talipes equino-varus and defect of toes in both feet, upon which he operated in 1920. Before operation the patient, who was manifestly very intelligent and had the will to persevere, had been able to do a number of things for himself, by using his feet, despite the absence of all digits, except a short great toe on the one foot and a long one on the other. It may here be noted that the deformity of varus of a moderate degree is rather an advantage than a drawback when the foot is to be used in lieu of a hand. Moreover, this boy was able to do a surprising number of things by opposition of his right shoulder and cheek. Between them he could grasp and use a pencil and even a small saw, and with them he learnt to seize and turn a door handle. The boy at the age of 12 could draw, write, carve wood, and weave rugs, besides washing himself and cleaning his teeth with the help of his feet. Yet he was not content to remain so unlike other boys and earnestly desired to be able to wear artificial arms and hands, if it were only for the sake of appearances. Finding from the inspection of radiographs that there was a rudimentary stump of each humerus concealed beneath the skin of the chest, although there were no axillæ, Dr. Mock decided to make use of these. By excellently planned and skilfully carried out operations he succeeded in freeing the rudimentary humeri and clothing them in muscle and skin, despite the fact that there was grave muscular defect. The boy gradually learned to move the stumps, and the result five years later is interesting as showing the connexion between function and development. The upper ends of the humeri and the glenoid fossæ, which before operation were only rudimentary, have now developed greatly after five years of exercise, and the boy is able to wear artificial arms and hands which he finds of considerable use.

The lessons to be learnt from this case are: first, that no matter how unpromising the condition, there is always a chance of benefit following well-thought-out and skilful surgical interference; secondly, that there is no knowing what development of the growing organism may follow on restored or new functions; and thirdly—and this is the most important of all—that as in war so in prosthetics the moral is to the physical as at least three to one. Dr. Mock does not specify the kind of artificial arm which was provided for his patient, and information on this part of the subject would be of considerable interest. The experience of those who had to do with the provision of arm prostheses during and after the war was most disappointing. It was found that in their daily life pensioners used even the most ingenious arms very little, if at all, and that only in the case of double amputation were they really useful except for rough work. Some of the most striking successes in the use of artificial arms have been achieved with very simple appliances. It is to be remembered, however, that the possibilities of usefulness of stumps are far less for the adult who finds himself suddenly mutilated than for the congenital case, whose growing organism develops in adaptation to its environment. In all cases, however, intelligence, the will to succeed, and what is colloquially known as grit, are the most valuable compensations to the congenital arm-cripple.

---

THE Rt. Hon. T. R. Ferens, of Hull, who recently gave £250,000 to the University of Hull, has now given £20,000 to found an institute for diseases of the ear, nose, and throat in connexion with the Middlesex Hospital.

---

THE Home Secretary gives notice that it is proposed to apply for an Order of the King in Council in pursuance of Section 8 (2) of the Dangerous Drugs Act, 1920, declaring that Part III. of that Act shall apply to veronal and the other drugs of the barbitone group in the same manner as it applies to the drugs mentioned in Subsection (1) of Section 8 (morphine, cocaine, &c.), and in pursuance of Section 7 of the Act to make regulations limiting the supply of the drugs to authorised persons or institutions or to persons for whom the drugs have been prescribed by a duly qualified medical practitioner.

---

THE Oxford University Press will shortly publish an illustrated monograph by Dr. Jamieson B. Hurry, entitled "Imhotep, the Vizier and Physician to King Zoser and afterwards the Egyptian God of Medicine." Imhotep or I-em-Hete was one of the earliest of known physicians and was recently the subject of an annotation in our columns THE LANCET, 1925, ii., 821).

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

---

## CLXVI.

## TREATMENT OF FRACTURES OF THE FEMUR.

UNDER the best treatment a patient suffering from simple fracture of the femur will be incapacitated from work for at least three months. In cases in which we fail to secure reasonable length and correct alignment some permanent disability is certain. It is therefore important that every practitioner, who may have to assume the responsibility of treatment of fractures of the femur, should be familiar with the use of splintage which is both simple and effective. Before the war the results of the operative and non-operative treatment of fractures was a subject of investigation by a special committee of the British Medical Association. In nearly every age-group operative cases showed a higher percentage of good results than non-operative cases. The suggestion to an unbiased observer was that operative technique would in time almost entirely supplant treatment by splintage. It is now generally agreed that as a result of the war the outlook is changed. Here fractures of the femur presented a problem which could not be solved by operation. The splints of the text-books got a fair trial and were found wanting. The minds of the greatest surgeons of all countries were endeavouring to devise means for fixation of the compound fracture of the femur, but only after two years did it become generally recognised that life, limb, and function could be best conserved by the use of a splint first offered to the profession by Hugh Owen Thomas, of Liverpool, almost half a century ago. During the latter years of the war it replaced all others. Its ready application allowed of its use in the front line. The fixation it offered diminished shock and prevented further injury to the tissues during transport, while the principle on which its efficiency depended was surpassed by no other in the special hospitals established for the treatment of these fractures at home and abroad. That it was effective is proved by the fact that a survey of 500 cases of compound fractures of the femur under treatment at orthopædic centres in this country showed an average shortening of less than half an inch. We may therefore assume that instruction in the use of the Thomas splint in fractures of the femur is safely established in all medical schools.

### *Splintage.*

Ideal splintage requires: 1. Replacement of the main fragments to their normal anatomical position. 2. Immobilisation of the limb so that there is no disturbance of the fragments in moving. 3. Avoidance of compression of the limb, and in the case of compound fractures easy access to all dressings. Its efficiency will be judged by the relative comfort it affords the patient during treatment and the end-results as regards function. I believe that the Thomas knee splint will meet these requirements for all fractures of the shaft of the femur below the upper third. Fractures of the neck of the femur, the upper third of the femur, and those directly involving the knee-joint may require special consideration. The deformities and disabilities following fractures inefficiently treated are almost constant, so that a knowledge of these is essential to guide us in our treatment.

### *Fractures of the Neck.*

It is not possible here to detail the symptoms and physical signs of partial separation of the epiphyses and bending of the neck of the femur in young adolescents. Where these are suspected X rays will reveal them, and their treatment follows the lines of treatment of fracture of the neck of the femur in the adult.

The common result of fracture of the neck of the femur is upward displacement of the trochanter with eversion of the limb. The X rays will show that the angle of the neck of the femur and the shaft has been reduced to a right angle, and if the fracture is intracapsular there will probably be non-union of the fragments. Pain either from non-union, adhesions, or arthritis of the hip often persists. The modern treatment of these fractures is based on a knowledge of the inevitable results of failure to reduce the fracture. Under an anæsthetic full extension of the limb is obtained by traction. It is then internally rotated to lock the fragments, and finally fully abducted in order to ensure the normal angle of the neck and shaft of the femur. This position is maintained by plaster-of-Paris for eight to ten weeks, when freedom of the limb in bed is allowed. We must still remember that weight-bearing will involve strain across and not through the fracture. Further treatment should therefore be exercise without weight-bearing for another six weeks, when a calliper splint may be carefully fitted so that no undue strain is placed on the neck of the femur. This should be worn for at least six months from the date of fracture.

### *Fractures of the Upper Third.*

The common results of malunion are flexion and abduction of the upper fragment. Here the upper fragment is short, deeply situated, and has strong muscular attachments which determine its position. Its direct control by splintage is not possible. Treatment therefore aims at approximating the lower fragment to alignment with the upper. Strong traction of the limb in the position of abduction, with fixation of the body from which these muscles arise, will allay their spasm and allow approximation and union of the fracture without deformity. This result may be obtained by: 1. The Jones abduction frame. By this means fixed extension in the abducted position is secured while fixation of the spine and hip results in relaxation of the psoas and iliacus muscles. 2. Fixed extension of the lower fragment in flexion and abduction by means of the simple Thomas knee splint. This was the method adopted by Pearson during the war, and in his hands gave excellent results. When the special bed employed by Pearson is not available the position of the pelvis should be stabilised by incorporating it and the sound limb in plaster-of-Paris.

### *Fractures of the Shaft.*

The common deformities resulting from malunion of fractures of the lower two-thirds of the shaft of the femur are: (1) outward angulation at the site of fracture; (2) sagging of the fragments; (3) internal rotation of the limb below the fracture.

The Thomas knee splint has now been recognised as the standard splint for the treatment of these fractures. I will therefore describe its application in detail. The limb having been shaved extensions are applied extending from the ankle to the middle of the thigh. A Thomas splint bent at the level of the knee-joint to an angle of 100°, with a well-fitting ring, is threaded over the foot and limb until the ring impinges on the tuber ischium. While the limb is held by an assistant a double flannel bandage 4 in. wide is fixed to the lateral bars by a clip at the site of fracture. This band should be sufficiently tight to ensure the normal anterior bowing of the femur when the extensions are tied to the end of the splint. Other suspensory bands are applied from the buttock to a hand's breadth above the heel. These should be sufficiently tight to support the limb, but not so tight as to render the band at the site of fracture loose.

We now have fixed extension of the limb, and experience has proved that under this influence muscle spasm relaxes and the fragments are easily guided into correct alignment. If undue pressure of the ring is complained of this may be relieved by utilising body-weight as a traction force. The bottom of the bed is raised 18 in. and the end of the splint tied to a vertical upright fixed to the bed frame. By this means the extension of body-weight is added to the fixed extension already obtained by means of the splint. Reduction of the fracture may be confirmed by X rays without disturbance of the splintage.

As soon as there are clinical signs of union graduated exercises of the knee may be allowed. This may be done while extension is maintained by means of a duplicate of the lower portion of the Thomas knee splint, hinged to the main splint at the level of the knee-joint. The extension and supporting bands are transferred to this, and gradually increasing movement of the knee allowed. At the end of eight weeks, if union feels firm, the splints may be discarded, and physiotherapy employed to restore the musculature and movements of the limb. Weight-bearing without a protective calliper splint should not be allowed until the X rays show definite trabeculation of bone at the site of fracture. In fractures of the lower third of the femur the special tendency to tilting backward of the lower fragment must be guarded against by increasing the degree of flexion of the splint at the knee, while maintaining fixed extension of the limb.

### *Fractures Involving the Knee-joint.*

These include T-shaped fracture of the lower end of the femur, separation of one condyle, &c. Where the nature of the fracture will not allow of the restoration of the normal alignment of the joint surfaces by external splintage operative reduction should be undertaken early. Instability of the joint and deformity on weight-bearing will result unless the normal level of the condyles is re-established.

### *Separation of the Epiphyses of the Lower End of the Femur.*

In children forward displacement of the lower epiphyses of the femur may result from indirect violence, usually forced hyperextension of the knee-joint. Reduction is not difficult. Direct extension is applied to the limb, followed by flexion of the knee-joint. The epiphyses having been reduced the position of 60° flexion of the knee should be maintained for three to four weeks. Gradual extension of the limb may then be allowed, no force being used.

During the war many complicated accessories were added to the Thomas splint. They often added to the comfort of the patient, but the effectiveness of the splint depended on the essential principle of fixed extension of the limb, which ensured length, while any tendency to persistent deviation of one fragment from the line of the other was easily controlled by flannel bands passing as required to the lateral bars.

The *Thomas bed splint* consists of an ovoid ring welded to two lateral bars extending to six or more inches beyond the sole of the foot, and uniting in a U-shaped depression to which the extensions are tied.

The *Calliper splint* is used to enable the patient to bear weight on a limb before complete consolidation of the fracture is established. It may be provided by cutting the lateral bars of the bed splint and bending the ends inwards, so that when these ends are inserted into a socket in the heel of the boot body-weight is still transferred to the tuber ischium, while walking is allowed.

The *Jones hip abduction frame* consists of two bars of iron (3/4 by 3/16 gauge for 20-in. frames), one perfectly straight, and the other abducted at a level with the hip-joint to an angle of 25° to 60°.

A full description of these splints, and several useful hints as to the details of their application, will be found in the text-book on "Orthopædic Surgery,"[1] by Sir Robert Jones and Prof. R. W. Lovett published in 1923.

## Special Articles.

## NATIONAL HEALTH INSURANCE: REPORT OF THE ROYAL COMMISSION.

WE published in THE LANCET of March 6th (p. 510) the most important of the recommendations of the Royal Commission on National Health Insurance. We now furnish some interesting passages from the report. The Commissioners state :—

### *The Fundamental Character of the Scheme.*

We have received very little evidence directed against the scheme as a whole, nor have we any reason to think that there now exists any considerable body of opinion adverse to the principle of national health insurance.

### *The Inequalities of Benefit.*

We received much evidence in criticism of the inequalities of benefit which result from the variations between the valuation surpluses of approved societies and of the confusion alleged to be consequent on the comparative freedom which societies enjoy in selecting and, indeed, in defining the content of additional benefits other than an increase in the rates of the cash benefits. . . . Other witnesses contended vigorously for the maintenance of the present system. . . . Some of those who advanced this claim relied on pledges given when the Bill of 1911 was before Parliament, to the effect that, to meet this difficulty, insured persons should be free to choose their own societies and the societies should have full control of their own surpluses. In this particular sphere, indeed, it became evident that we had to recognise the existence of opposed and apparently irreconcilable opinions held in each case by schools of thought whose views were entitled to respect and consideration.

### *General Satisfaction with the Scheme.*

We can say at once that we are satisfied that the scheme of National Health Insurance has fully justified itself and has, on the whole, been successful in operation. The workers of this country have obtained under it substantial advantages, in particular by securing the title to free medical attention and medicine whenever and as soon as these are required, and by the proportionate diminution, to the extent of the cash benefit granted, of their anxiety as to the loss of wages during illness.

### THE DEVELOPMENT OF THE HEALTH SERVICES.

Medical benefit has been in operation for 13 years; of the other branches of medical service some preceded, others followed its introduction. In all these activities we have found, speaking broadly and with full consciousness of its limitations, such a contribution to the health and well-being of the community that we feel sure that a steady expansion in these services will mark our future social history.

### *Scope of Medical Benefit.*

The effect of the provisions of the Act was that the insured person was entitled to receive from one doctor, and from one doctor only, the whole of "medical benefit" whatever that phrase might mean. In these circumstances it appeared to the legal advisers and to the department that the scope of medical benefit must be construed as limited to services within the competence of the average general practitioner. Further, though the medical lists included a certain number of men with special experience, whose competence in certain directions was therefore above the average, it was felt that if all doctors were to receive the same rate of remuneration, as practical considerations were found to require, a uniform obligation and a uniform content of service were implied; and that it would not be equitable to require one man, because he happened to possess some special skill, to render a wider range of service than was required from the majority of his fellow practitioners engaged under the insurance contract.

Though this limitation of the service has been from time to time commented upon and though on all sides a fuller conception of medical benefit has been urged upon us by witnesses, no attempt to challenge it in the courts has ever been made during the 13 years of its operation. We may fairly assume, therefore, that it is valid on legal grounds and we recognise the general and administrative reasons for the restriction in the regulations.

### *The Value of Medical Benefit.*

As to the quality of the insurance medical service we will restrict ourselves to a citation of some representative extracts from the evidence, prefacing these quotations with the remark that the general acceptance of the system during the last 13 years, the absence of any substantial volume of criticism of it apart from the question of scope already referred to, and the wide demand for its extension, are in themselves evidence of a favourable kind.

### *Private and Insurance Service.*

The assertion that doctors are comparatively inattentive to their insurance patients—a statement more common in unrestrained conversation and in letters to the press than in formal evidence—is peculiarly difficult to test, inasmuch as, in the nature of things, it almost necessarily rests on vague impressions or sporadic and unrepresentative incidents. It is, perhaps, proper to observe that in a service comprising 15,000 doctors it is impossible to postulate that all will, at all times and in all circumstances, maintain a superlative standard of efficiency and care. It must needs that offences come. The medical profession, like every other craft and calling, can claim no immunity from the intrusion of undesirable and unworthy elements. Nor does this imply any disrespect towards an honourable profession; it is merely an acknowledgment of their common humanity. Isolated cases of negligence and carelessness, therefore, prove nothing; such occur in private practice also.

We can say confidently that adverse forecasts have been falsified and that medical benefit has proved in practice a successful and most valued factor in the advancement of the health of the nation.

### *Ophthalmic Benefit.*

It is not within our province to consider the arguments for or against the prohibition of the testing of eye-sight by persons other than medical practitioners. But as to the provision to be made for insured persons as part of the Health Insurance Scheme, we consider that a satisfactory solution could be found in connexion with a proposal which we make elsewhere directed to the provision of a specialist medical service as part of medical benefit. Such a specialist service would include ophthalmic specialists whose services would be at the disposal of insured persons requiring them, and the function of the optician would thus, in the case of insured persons, be limited to the making-up of the spectacles prescribed by the eye-specialist.

### *The Local Medical and Panel Committees.*

These bodies have proved a valuable element in the medical side of the insurance scheme. The principle of having in each area a representative body of medical men, to whom professional questions are referred and by whom many of the administrative problems affecting the insurance practitioners are considered, has evidently been acceptable to both lay and professional opinion. . . . Under such an extension of medical benefit as we recommend, and even more so in any larger developments of the future, the two committees will necessarily tend to coalesce and become, if they are continued, the single expression of professional wisdom in the area. We do not doubt that they will be continued in any immediate developments, and equally we see in them the hint of a local professional committee working side by side with the single local health authority in all parts of the country.

### *A General Public Service—ultimately.*

We are of opinion that the difficulties of a composite support to a completed medical service from insurance funds as well as from grants and rates would be so considerable alike in their financial, administrative, and social aspects that some more practical solution must be sought. In particular we feel sure that the wider the scope of these services, the more difficult will it be to retain the insurance principle. The ultimate solution will lie, we think, in the direction of divorcing the medical service entirely from the insurance system and recognising it along with all the other public health activities as a service to be supported from the general public funds. Consideration would have to be given to the question of the classes of society for whom the service would be available and whether it should be so available on a free basis or with payments by insurance or otherwise. These, however, are problems which need not—perhaps cannot—be solved now, but may be fitly left over for those who, unlike us, will approach at close range to the great question of the public health service of the future.

### THE FINANCIAL BURDEN OF THE EXISTING SOCIAL SERVICES.

We feel that there may come a time, and that in fact there has come a time when the State may justifiably turn from searching its conscience to exploring its purse, and that in connexion with our present reference we are entitled to direct attention to this grave problem, and to frame our recommendations in the light—or the darkness—of the economic condition of the nation. We therefore make the definite recommendation that only such extensions or modifications as involve no expenditure or can be met within the present financial resources of the scheme, should be considered as immediately practicable.

### *Continuation of the Approved Society System Recommended.*

We do not ourselves think that the best interests either of the State or of the insured population would be served by a vast amalgamation of all the resources of the scheme in a common fund administered from the centre, and for the reason given we are satisfied that such an amalgamation would create as much discontent as it would allay. From this point of view, therefore, we have come to the conclusion that a system of self-governing bodies is to be preferred and should be retained.

### *The Problem of In-Patient Treatment in Hospitals.*

We think that the present arrangements, under which approved societies may give financial assistance to the hospitals under their schemes of additional benefits or by way of donations under Section 26 of the Act (with a certain modification in the latter which we recommend), may be continued, but that no general provision of hospital treatment can be at present contemplated within the insurance scheme. We fully appreciate the great work the hospitals are doing alike for the insured and the uninsured, and we do not underrate their financial difficulties. But both on grounds of finance and policy we accept the view of the Ministry of Health that an extension of this nature must be left over for future consideration.

### *Reactions on Efficiency of General Practitioners.*

In a system under which specialist services and general practitioner services were welded into one scheme, the conditions of general practice would be completely changed. The mere obligation to furnish the expert with a statement of the case would have a valuable and educational influence in constraining the practitioner to give definiteness to his ideas. When he had to prepare a statement to come under the critical eye of the expert he would, by that mere fact, become alive to defects in his conduct of the case, which he had not previously realised. The indirect benefit resulting from such a requirement has, we are informed, already been seen in the work of the regional medical staff. Again, the specialist's report will often reveal to the practitioner points in diagnosis or treatment which he might have overlooked. It will thus add to his knowledge by enabling him to assimilate the expert view of his cases as they come along. In all these ways the provision of a specialist service would operate as a most valuable form of post-graduate instruction and would probably be gratefully welcomed by the isolated general practitioner. The educational benefits so resulting would not be confined to the insured persons, but would be extended to the whole range of general practice.

### *Estimate of Cost of Provision for Persons able to Travel.*

The estimate has been based upon inquiries made by the regional medical officers and on statistics published by certain hospitals. The conclusion of the Ministry is that for the insured population of 13½ millions in England and Wales the cost would not, on the lowest assumptions as to number of persons referred and other factors of cost, fall below £487,000, and would be unlikely to exceed £840,000 per annum. This is, of course, a wide difference. It is mainly due to different assumptions as to the proportion of the insured population that would be referred to the specialist.

### *Estimate of Cost of Home Service.*

On the basis of such information as is at present available the Ministry have estimated that the cost of domiciliary consultant services would probably not exceed £250,000. We recommend that the working of the arrangements for the provision of a domiciliary consultant service should be closely watched by the central department, particularly in the early stages, to ensure that the system is not resorted to by lax or negligent practitioners in cases where no real doubt arises in regard either to diagnosis or treatment.

### *General Summary of Cost.*

The maximum annual cost of a scheme of expert out-patient services such as we have outlined, including all the work for a population of 13,500,000, is as follows:—

| | |
|---|---|
| Specialist services .. .. .. | £840,000 |
| Bedside consultations .. .. | £250,000 |
| Laboratory aids .. .. .. | £100,000 |
| Total .. .. | £1,200,000 |

(This is for England and Wales, but not Scotland.)

### *Dental Treatment.*

We have come to the conclusion that no change should be recommended at present in the main provisions for dental treatment. A complete dental service would be eminently desirable. But it would cost about £4½ millions a year, or 1½*d.* on the contribution. A partial service has, as we have indicated, many defects and difficulties, medical as well as administrative. Any reasonable partial service would cost about £2½ millions a year.

### *A Regional Dental Staff.*

As the activities of the regional dental service would in very considerable measure tend to protect the expenditure of the approved societies on additional benefits, and as the greater efficiency of the treatment would in the long run tend to conserve the benefit funds, we think it only fair that a substantial proportion of the cost of the regional dental staff, if it is established, should, as in the case of the regional medical staff, be borne by the approved societies concerned.

### *Transfer of Powers and Duties to Local Authorities.*

The conclusion we come to is that insurance committees should be abolished, and that their work, very much in its present form, pending any radical remodelling and unification of the health services, should be handed over to committees of the appropriate local authorities with possibly a coöpted element. We do not enter into any details as to what is the appropriate local authority, as this question is dependent on the results of the deliberations of the Royal Commission on Local Government now sitting. Until the lines on which the general framework of the local government of the country is to be remodelled are known, any specific recommendations would be useless. If our recommendation in this matter is adopted, we think it may safely be assumed that provision would be made for the absorption of the staffs of the present insurance committees.

### *The Complaints Machinery.*

On questions of procedure for dealing with complaints against practitioners, the British Medical Association made certain suggestions for the alteration of the regulations, among others, that an appeal to the courts should be possible not only on the ground of improper procedure as at present, but on the ground that the penalty inflicted was out of proportion to the offence; and that in the case of proposed removal from the service the practitioner should have the right of appeal to a duly constituted central professional committee, and that the Minister of Health, in cases where this right was exercised, should not be able to remove the practitioner from the service unless the central professional committee advised this course. . . .

The former proposal involves placing upon the courts the responsibility for deciding questions of a kind which, in our opinion, can be more appropriately decided by a Minister who is answerable to Parliament for the manner in which he exercises his discretion. The latter proposal we are also unable to accept. We appreciate that removal from the medical list may be, and usually is, a very severe penalty, but it has to be remembered that the ground of removal is that the retention of the practitioner would be prejudicial to the efficiency of the medical service of the insured persons, and it would, in our judgment, be contrary to sound constitutional practice that the Minister's responsibility to Parliament for the maintenance of an efficient service should be delegated to an outside body, whether professional or otherwise.

With regard to questions relating to the propriety of any particular method or line of treatment, we agree that where it appears that a practitioner has exercised his judgment to the best of his ability, his professional skill having been, in the words of one of the witnesses, "carefully and properly given to the patient," the Minister should not go into the question whether the line of treatment which was adopted is in accordance with any particular professional doctrine as to what is or is not the best line of treatment in such cases. From inquiries that we have thought it necessary to make we gather that the Minister accepts this view and would not regard it as part of his duty, when considering, as the regulations require, whether a proper standard of treatment has been given, to enter into questions on which professional opinion might differ as to the efficacy of particular methods of diagnosis or treatment. This, however, is subject to the qualification stated, that the practitioner has, in fact, exercised his professional skill with reasonable care, and this appears to be a matter of which cognisance must be taken in the exercise of the Minister's disciplinary powers. . . .

As to inquiry cases, if the Minister decides that the facts established by the Inquiry Committee do not warrant removal, but do appear to call for some lesser penalty, a new issue arises and considerations may properly be taken into account which were not relevant to the major issue of removal from the list. For this reason we think that before any penalty other than removal is imposed, the doctor should be given an opportunity of a further hearing.

### *Employed Contributors: The Income Limit.*

On the question of the income limit for insurability, we have carefully considered the proposal of the British Medical Association, that such a limit should be fixed for manual as well as non-manual workers. We are definitely of opinion that such a change would be undesirable. We think that the present principle which draws a firm distinction between manual and non-manual labour beyond a certain point is sound, inasmuch as the manual worker, whatever his earnings at any moment may be, is generally subject to economic conditions which render an insurance provision highly desirable. . . .

The only practicable method of dealing with this administrative difficulty would be to determine prospectively for a certain period an insured person's title to benefit by reference to his financial position retrospectively, and it hardly requires to be pointed out that the adoption of such a solution might have the effect, and indeed would not infrequently have the effect, of granting an insured person medical benefit while his earnings were high, and withdrawing it in the subsequent period when his earnings might be reduced. This result would curiously defeat the whole purpose of the suggestion.

### *Proposed New Additional Benefits.*

We have been informed by several witnesses that there is a pressing demand for the inclusion of payments for massage and electrical treatment as an additional benefit, and we have received evidence which convinces us that the provision of this benefit would materially assist in the promotion of earlier recovery in the case of persons suffering from certain types of incapacity. We would refer particularly to the evidence given before us by Dr. Smith Whitaker, and that given on behalf of the Chartered Society of Massage and Medical Gymnastics. We recommend, therefore, that this benefit should be added to the list.

### *Inquiries into Excessive Sickness.*

We have come to the conclusion that the penal provisions directed against the local authority or the employer are useless as a means to further the end which the section has in view and that they should accordingly be eliminated. But we think that the bodies responsible for the local administration of medical benefit to insured persons should be given power to institute inquiry into cases of excessive sickness brought to their notice, and that for this purpose they should have access to the medical records collected under the Health Insurance Scheme.

### *Medical Institutions.*

After careful consideration of all the evidence before us we think that this method of providing medical attention and treatment is an anomalous feature in a scheme of which the cardinal principle is a contract between insurance committees on the one hand and individual independent doctors on the other, and that it introduces lay control over professional men in an undesirable form. On the other hand, we consider it necessary to have regard to the recognition by Parliament of these institutions at the time when the scheme was introduced, and to the fact that there is no evidence of failure sufficient to justify a recommendation on our part that the recognition of the institutions for the purposes specified should now be withdrawn. The original Act restricted recognition to those institutions then in existence, clearly designing that this method of providing medical benefit should be exceptional and should be regarded as an unavoidable inheritance from the past.

### *Contracting Out.*

We recommend that Section 24 (3) of the Act should be amended so as to debar any insurance committee, or local authority succeeding to its powers, from sanctioning the use of any organisation for the purpose of "collective own arrangements," and to provide that the provisions of the subsection shall not be applied otherwise than to individual insured persons. We wish, however, to make it clear that our recommendation does not apply to cases in which nurses or other resident employees of hospitals normally receive medical treatment and attendance from the medical staffs of the hospitals in accordance with the terms of their employment.

---

VICTORIA HOSPITAL, KEIGHLEY.—Last week Princess Mary opened a new electro-medical block. The extension comprises a radiographic room, treatment room, dark room for developing plates, dressing cubicles, offices for records, and a doctor's room. The Princess took a radiogram of the matron's hand and saw it developed.

# PENSIONS FOR HOSPITAL OFFICERS AND NURSES.

## I.

AN explanation of the draft scheme of pensions for hospital officers and nurses will be helpful to the many medical men who are interested, directly or indirectly, in the subject. The outline of the scheme which follows contains little detailed criticism, especially of the financial aspects; a subsequent section deals with these, although certain comments will be found here, it being impossible even to sketch the outline without recognising the grave difficulties of finance involved. For these include the serious liability to be suddenly shouldered by the hospitals, and the problems presented by the attempt to adapt a scheme, on the one hand, to existing officials of mature age and long service, and, on the other hand, to that often transitory figure in hospital life, the nursing probationer; "once a nurse always a nurse" is by no means an accurate description of this class, where the actual work often brings disillusionment, or marriage leads to its abandonment.

The scheme represents a great ideal and, even if it prove to be impracticable to build the entire edifice at the outset, it may well be possible, and financially prudent, to erect a substantial wing of the structure to-day, to which extensions may afterwards be made as funds permit. Fundamentally, it is based upon the same lines as those of the now well known and satisfactory Federated Superannuation System for Universities; and rightly so, for in both cases a combined scheme is required for a group of independent institutions forming together a common professional service, within which migration from one institution to another is fairly frequent. An insurance policy, whether with or without death benefits—i.e., an endowment assurance or a deferred annuity—is to be taken out for each person concerned in order to provide the ultimate pension, such policy being, as it were, attached to the individual and clinging to him, within certain limitations, whether he (including she) move from one institution within the scheme to another also within it, or whether he leave hospital service altogether; such policies will be increased *pari passu* as salaries increase with the lapse of time, and are to be paid for by annual premiums, these to be effected with one or other of certain chosen insurance offices which will be placed upon a panel, selection to follow in due course. The amount of annual premium payable is to be 15 per cent. of the salary and emoluments (which latter term roughly means the money value of board and lodging) of the individual, and it is proposed that two-thirds of this—that is to say 10 per cent.—shall be paid by the hospital, and one-third, 5 per cent., by the individual.

Officers' pension policies are to mature at age 60, so that retirement can take place then, or later, in accordance with the regulations of the hospital concerned. Premiums cease in any event on attainment of that age, but, if retirement be deferred, can be accumulated thereafter at compound interest, the eventual pension thus, of course, being augmented. In the case of nurses, the scheme fixes the retiring age at 55.

### *Hospital Officers.*

There are certain salary limits suggested. Dealing first with the officers, it is proposed that where salary and emoluments are below £100, the officer should be ineligible; where between £100 and £160, that entry should be optional; and where over £160, compulsory, so far as all future entrants into hospital service are concerned. A maximum limit would doubtless have to be agreed in practice, so that it might be possible for hospitals to give substantial increases in salary to senior officers late in life without necessarily forcing up the pension scale to an uneconomic figure. When an officer leaves one hospital for another under the scheme, or not, he takes his policy with him; in other words, he takes the accumulation, not only of his own contributions, but that of the hospital's contributions; it is held that, in the long run, this interchangeability will result in a roughly equitable distribution, and that hospitals will gain in some cases what they lose in others. It may be so, but it might well prove that those hospitals which train their personnel best would lose more than they would gain by this rule, valued employees passing with inconvenient frequency to other institutions.

Officers leaving hospital service altogether within five years of joining would only take the benefit of their own contributions, but any so leaving after five years' service would take not only their own, but the whole of the hospital's contributions, subject only to the institution having some voice as to the way in which the total contributions should be applied so as to benefit the individual most suitably. A fundamental theory of the drafted scheme emerges—that the underlying principle should be to regard the hospital's contribution towards the ultimate pay as being in the nature of deferred pay, fairly earned by the officer year by year. Once grant that, and his right to take such contributions with him can be granted also; but, in that case, the scheme must be admitted as involving a definite increase in the effective salary of every officer, which in turn is an increase in the hospitals' working expenses, and must be fairly faced as such. That aspect of the situation will be discussed in the next article, when the financial side of the whole scheme will be dealt with; for the moment, the recital of the salient points of the scheme claims attention.

### *The Nursing Staff.*

Turning to the nursing staff, the scheme recognises that, during the first years of employment, nurses are, in part at least, only learners—a natural line of cleavage which, in a large view, runs through the whole of hospital service and far beyond the limits of the nursing staff; the difference between learner and teacher is all important when we have to consider what may be, in equity, the onus upon the hospital to contribute to the ultimate pensions in individual cases. It is therefore proposed that, in the case of members of the nursing staff, the contributions both of the hospital and of the nurse in respect of the service rendered during this training period should not be used to procure a policy, but should be held, as it were, in suspense. They are to be placed on deposit during the training period at compound interest; thereafter, when the training period is over, the amount thus standing to the nurse's credit would be used to take out the usual policy, any balance over and above the 15 per cent. basis being used as a single premium to increase the benefits. It is an obvious comment here to say that it is sanguine to assume that probationers with a salary of, say, £25 a year, will readily part with 5 per cent. of their total salary and emoluments, say, £3 15*s.* a year, in this way. A young woman may be theoretically receiving annually £75, in "meal and malt," but she does not regard the £50 value of her board and lodging as money, but looks rather at her actual cash wage, which, indeed, is all she has to spend. She will consider £3 15*s.* out of her £25 a very big bite.

Those, however, who cease altogether to follow the nursing profession within five years of entry as probationers would take away their own contributions, the hospital receiving back from the insurance office those which had come from its coffers, and the sum, if small, representing compulsory savings would be of use to most young women with little money to spend. The hospital is more concerned with the fact that nurses leaving the profession altogether after that five-year period had expired would take with them the full accrued benefit of all the contributions, hospital's and individual's, subject only to the fact that it is suggested that some nursing committee or body of that kind should prescribe the form in which it would be in the best interests of the individual that these benefits should be taken—for instance, whether in cash or in the form of a modified pension to the extent which the past payments would suffice to provide. The important and serious fact, however, from the hospital's point of view, is that the institution would in all those cases lose its own money. And the warning note should be sounded that the very existence of a claim to a sum that could be regarded as a small dowry may tend to increase the number of those who may drop out of hospital life. Some nurses who would normally have left earlier, according to their own inclination, and, indeed, perhaps to the hospital's advantage, may be moved to hang on until the end of the fifth year; others, though efficient, and perhaps happy in their calling, might find these accumulations an inducement to leave, and the marriage rate would be increased, if to the advantage of the State certainly to the disadvantage of the hospitals.

### *The Position of Existing Officers and Nurses.*

The position of existing officers and nurses is vitally affected by two matters—one, that of future contributions from those entering in mid-career and later life, and two, that of the treatment received in respect of past service. The scheme suggests that the future contributions in respect of an existing officer or nurse should be the same percentage as for new entrants, the pension so purchased being, of course, smaller in accordance with nearness to the age of retirement. The argument employed is that such contributions, so far as they went, "would relieve the hospital of part of the liability to provide for the pension when it became due." The very words used predicate that a definite liability already exists, and, if that be conceded, it seems not unlikely that some existing officers and nurses may ask shrewdly why they should now begin to contribute annually out of their income in order to help the hospital to provide pensions which, by admission, would have had to be provided for them anyhow.

Unquestionably it would be far too expensive to attempt to meet the difficulty in advance by paying over to the insurance offices lump sums equivalent to the contributions which would have been made year by year had the scheme existed throughout those periods of past service: but it has been suggested that, as all those existing officers who did join the scheme would be paying one-third of the cost of the pension in respect of their future service, the hospitals should guarantee that the actual pensions eventually should never be less than would have been granted had the scheme not existed, a guarantee to be given not only to those who join, but to those now above the age limit. This, again, seems a suggestion somewhat vaguely sketched, for it would then be necessary in each hospital to set down in black and white what that hypothetical pension would have been; and, in taking such a very serious step as guaranteeing a definite annuity at a definite date, in place of a shadowy recognition of a moral obligation to provide something some day, the hospitals would be compelled to count the cost carefully lest they should promise more than they can fulfil.

When, in the sequel, some actual figures are given, not only will the cost to the individuals be shown, but some measure of the heavy burden which the full scheme would surely place upon the hospitals. All who have the interests of the hospitals at heart will see that an effort should be made to offer constructive rather than destructive criticisms with regard to a development of hospital service which in some form or another is overdue, and the scheme may still fortunately be considered as in the Bill stage rather than in that of the completed Act. That something must be done to improve the status of the nursing profession is a general admission; that something should be done to give a greater feeling of security with regard to their provision for old age to that hard-working class, the permanent hospital officials, is felt to be desirable; and that something may be done to inaugurate a better state of things is admissible. But there is always that insistent question of ways and means, and it is not generally possible to carry out a whole ideal programme at the start.

(*To be continued.*)

## MEDICINE AND THE LAW.

### *Meat in Open Windows.*

AN educative value attaches to the recent prosecution of some Deptford shop-keepers for failing to protect from possible contamination meat exposed for sale. According to a report in the *Times*, the terms of the summons taken out by the borough council charged them with neglecting to take steps to guard against the contamination by flies of meat exposed for sale, and to place the meat so as to prevent mud, filth, or other contaminating substance being splashed or blown thereon. According to the evidence of the medical officer of health, in one case the meat was exposed on a stall in the street, in another bacon was unprotected in a shop window, in a third bacon was lying behind an open window "without gauze or covering as advised by the Ministry of Health." The witness said he required closed windows and a gauze covering. For the defence, it was, of course, pleaded that the covering of meat at all times was impracticable. The magistrate's decision was that the meat was exposed to mud-splashing, but that there was no proof of actual splashing. The ideal, he said, was to be found in the medical officer's recommendation, which was not enforceable at present. It was not necessary to have glass windows. A technical offence had been committed; he therefore imposed a nominal penalty of £1 with an order for two guineas costs. From the public point of view it is valuable that shop-keepers should be set a high standard, but it is not satisfactory that prosecutions should be undertaken to enforce a standard which rests only on advice from the Ministry of Health or on recommendations from the medical officer. The law should be made plain, and it should be known as widely as possible, whether it depends upon a Public General Act, a Local Act, a regulation of the Ministry, or a by-law of the local authority. While the report of the case will educate both the shop-keeper and the public as to the danger of contamination, it seems to leave the legal position remarkably indefinite.

### *Eggs: Description as New Laid.*

Prosecutions under our sale of food legislation for the offence of selling food to the prejudice of the purchaser and "not of the nature, substance, and quality demanded" raise issues which are usually matters of simple fact. In a Norfolk case, heard at the beginning of this year and reported in the *Analyst*, the facts were that an egg-dealer bought 18 eggs of which some had admittedly been preserved in water-glass. There was a question whether they had been sold as "new laid," and, if so, whether an egg which had been preserved in water-glass had necessarily lost its nature and substance. The prosecutor's evidence was that, when the eggs were offered him, he remarked that they looked like water-glass, but that he was reassured by the seller's agent and then said he would take them as new laid, and that, if they were not new laid, the seller would hear more about it. This was construed as a demand for new laid eggs, and it was clear that the articles were not at any rate of the quality demanded. The magistrates unanimously convicted, and a fine of £5 was imposed. The defence that preservation of eggs is not adulteration was not particularly relevant, nor was the mention of the Sale of Food Order, 1921. That Order refers to eggs imported into the United Kingdom, and forbids their sale (wholesale or retail) "as fresh eggs or new laid eggs or under any description of which the words 'fresh' or 'new laid' form part" unless the description also includes the word "imported" or a word or words disclosing the country of origin. The Order, it may be added, is a survival of the days of food control. Parts I. (sale of bread) and III. (labelling of imported produce) of it are annually continued by the Expiring Laws Continuance Act in default of a properly considered permanent effort of legislation. As the country is unenthusiastic over the continuance of these relics of D.O.R.A. that effort might now be made.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *The Medical Register.*

THE *Irish Times* published last week a document stated to contain the proposals put before the Free State Government on behalf of the medical profession with a view of settling the question of the Medical Register. The document was accompanied by a series of notes purporting to explain its history and meaning. On the following day the same journal printed a letter from Mr. R. C. B. Maunsell, President of the Royal College of Surgeons in Ireland, in which he stated that the document published by the *Irish Times* was not that submitted to the Government, but a verbatim copy of certain rough notes brought by Mr. Maunsell himself before the medical committee The paper was confidential and had only been in the possession of some eight or ten persons. In Mr. Maunsell's opinion its publication was likely to hamper the negotiations between the Government and the medical profession. It is unfortunate that some one should have been so careless or so mischievous as to allow a confidential document to reach the press. Intrinsically the document is of interest since, as Mr. Maunsell admits, it forms the basis of the proposals submitted to the Government. It would be unfair to discuss its features in detail, but the underlying principles are that: (1) The General Council should not be disturbed in its present activities; (2) a Council and a Register for the Free State should be established; (3) any citizen of the Free State wishing to practise therein must be registered in the Free State Register; (4) any person not a citizen of the Free State wishing to practise therein must be registered either on the Free State Register or on the General Register. It may be agreed that these proposals seem to meet the demand of the Free State Government for an independent Register, and at the same time to protect the interests of the Irish medical schools.

### *Dinner of the Royal College of Surgeons in Ireland.*

The Charter Day dinner of the Royal College of Surgeons in Ireland was held last Saturday evening in the hall of the College, the President, Mr. R. C. B. Maunsell, in the chair. His Excellency the Governor-General was the principal guest, and over a hundred sat down to dinner. In addition to the President and the Governor-General, among the speakers were Lord Glenavy, Sir Thomas Myles, the Chief Justice, the President of the Royal College of Physicians, and the President of University College, Dublin.

### *King's Professorship of Materia Medica and Pharmacy.*

The vacancy in the King's Professorship of Materia Medica and Pharmacy in the School of Physic in Ireland, left by the appointment of Dr. T. G. Moorhead to the Regius Professorship of Physic, has been filled by the election of Dr. Robert J. Rowlette, F.R.C.P.I., who has been Professor of Materia Medica and Pharmacology in the School of the Royal College of Surgeons in Ireland since 1921.

### *Honorary Degree at Dublin University.*

The Senate of Dublin University has passed a grace to confer the honorary degree of M.Ch. on Sir Berkeley Moynihan.

---

THE LATE DR. A. LINDSAY.—For the last five years Dr. Alexander Lindsay, who died on Feb. 25th, had been living in retirement at Cricklewood. He was born 66 years ago in Ramelton, Donegal, and was educated at Queen's College, Belfast, and at Trinity College, Dublin, where he graduated as M.D. R.U.I. in 1883. Soon afterwards he went into practice at Burslem, Stafford, where he built up a considerable practice. Later he moved to Leyton, and again, some 17 years ago, to Kensal Green, where he remained at work until 1910. Wherever he went he left memories of his kindly personality. Dr. Lindsay married the daughter of Mr. Frederick Coates, of Hoddesdon, Herts, who died in 1913, leaving no children.

### EMETINE IN THE TREATMENT OF HEPATIC ABSCESS.

*To the Editor of* THE LANCET.

SIR,—Further to my letter on this subject which appeared in your issue of Jan. 10th, I would like to add some of the arguments on which I base my conviction that emetine alone is sufficient to cure cases of hepatic abscess.

1. *Pathology.*—In the first place had the condition been called anything but an abscess and had ipecacuanha been properly appreciated as a therapeutic agent, it is very doubtful if surgical intervention would ever have reached its recent, but I trust fading, importance in these cases. In its origin the "abscess" is secondary to bowel infection; it is not circumscribed; its inner surface is extremely irregular; its contents are sterile; the causative organism is in the tissues and, in fact, from every point of view it is exactly analogous to a gumma. People obsessed with the pyogenic abscess idea find it difficult to believe that the absorption of the contents of "hepatic abscesses," large and small, is possible. A little reflection should lighten this difficulty. For instance, it would be interesting to compare the cross-section of the myriad lymphatics of the liver with that of the aspirating needle.

2. *Diagnosis.*—It will be a sad day indeed for tropical practitioners if the dictum is accepted that aspiration is essential before the diagnosis of hepatic abscess can be made. I know that such a measure need not be necessary, as I have published the record of a case in which, though unproved by aspiration, the abscess ruptured two hours after treatment was begun. Would Dr. Manson-Bahr also require that a *psoas abscess*, another analogous condition, should be aspirated before the diagnosis could be made, and if not aspirated would he classify the case as unconvincing if and when the contents were absorbed in the course of treatment at, e.g., the Alton Cripples' Hospital?

3. *Treatment.*—I maintain that aspiration with evacuation of an hepatic abscess introduces a definitely deleterious factor and upsets all the natural processes of elimination. The direction of flow of the defence forces, so long as the amœbæ are alive, is centripetal, but once the amœbæ are killed the direction becomes centrifugal unless the contents are forcibly evacuated. In this case the flow remains centripetal because nature abhors a vacuum.

I have demonstrated, and many cases from the literature confirm my statement, that emetine alone is sufficient to cure cases of liver abscess. Aspiration, though a handicap, does not ultimately prevent cure, but once this operation is performed the result, even though it is happy in a large number of cases, is not obtained in the quickest, the most certain, and the most humane way possible. Finally, it is well known that abscesses, especially in the earlier stages, are often multiple, up to 25 per cent. has been stated, so that it is fair to ask if anyone could possibly be sure that all the abscesses had been reached and evacuated by the aspirator, and if not, as often occurs, cure results, is it not perfectly obvious that the abscess, which escaped the needle, has recovered, thanks to the emetine, which even the most surgically minded uses in association with his aspirating needle. If this is so, why put the patient to the pain and inconvenience of aspiration? Why not leave all the duty to nature and emetine.

In conclusion I would add two further points which my experience has taught me: (1) That emetine gr. 1 for 12 consecutive days is not the best method of giving the drug in liver abscess cases or for dysentery.

(2) That the larger the abscess and the longer it has lasted the easier, relatively, it is to cure with emetine only. I am, Sir, yours faithfully,

V. S. Hodson.

London, W., March 19th, 1926.

⁂ We have submitted Dr. Hodson's letter to Dr. Manson-Bahr, who replies as follows:—

"Dr. Hodson is correct in stating that many observers agree with him that emetine therapy acts beneficially in liver abscess and that it has sometimes appeared to have rendered operative interference unnecessary, but it is extremely difficult, as I think most men who have had sufficient experience will agree, to distinguish actual formation of amœbic pus from an amœbic hepatitis, in which invasion of the liver tissue by entamœbæ without pus formation has taken place. Aspiration is the only method capable of settling this question. The actual performance of aspiration is a simple matter and is certainly not attended with any more risk than the tapping of a pleural cavity; it is certainly a method equal in its diagnostic importance and therapeutic effect.

"The question at stake is the size of the abscess or abscesses and the results of the absorption of such a large amount of toxic matter on the individual. If a grave degree of toxæmia is present, as is usually the case, the sooner the pus is evacuated the better for the patient. It seems to me a very untherapeutic attitude to force an already toxic subject to absorb a large amount of dead tissue from his liver through his lymphatic channels, when a much more rapid and pleasant method is at hand. A liver abscess may be a comparatively trivial or it may be a very serious disease. When there has been formation of a large amount of pus (four pints or more) respiration is severely hampered and displacement, with consequent embarrassment, of important organs, such as the heart, may take place (as in a very serious case under my care at the present time).

"Surely Dr. Hodson does not credit emetine with such miraculous qualities that a few grains will suffice to dispel several pints of dead tissue and thereby relieve pressure on vital organs, nor can it possibly lessen the amount of septic absorption which is taking place. The cases quoted in my original paper with Dr. Morris (The Lancet, Jan. 9th) are two specific instances where, firstly, emetine therapy had failed to prevent the recurrence of an abscess, and, secondly, had failed to prevent the re-accumulation of pus in an abscess which had already been drained.

"It is probably unwise to dogmatise at present on the action of emetine in abscess of the liver. Other drugs act in a similar mysterious manner; quinine does not cure *every* case of malaria, nor salvarsan every case of syphilis; but to assert that the larger the abscess and the longer it has lasted the easier it is to cure with emetine, appears to be in direct contradiction to clinical experience."

## THE LOCALISATION OF SMALL FOREIGN BODIES: A CASE.

*To the Editor of* The Lancet.

Sir,—A few months ago I was asked by a young man to remove a glass splinter from his heel. He informed me that he had trodden on some broken glass about two years previously, all of which had been removed at the time save this small fragment. That a subsequent unsuccessful attempt at removal had occupied two hours under general anæsthesia, and that, since the splinter gave him pain and disability, he wished, if possible, to have it removed before proceeding to East Africa.

The following method of localisation proved so helpful on that occasion, and has been so since in the case of embedded needles, that I venture to record the procedure. Three marks were made with a skin pencil from side to side, encircling the heel. Over these marks were placed three pieces of fine silver wire, fixed in position with adhesive strapping. A stereoscopic radiograph was then taken. This localised the fragment relatively to the skin pencil marks. The skin of the foot was now prepared for operation by the iodine method and, using local anæsthesia, two hypodermic needles were inserted at right angles to each other, down to where the fragment was judged to lie in relation to the pencil marks. The foot was now wrapped in a sterile towel and another stereoscopic radiograph taken. This showed the position of the fragment relatively to the hypodermic needles, the vertical one having passed just anterior to it and the horizontal one immediately above it; it lay in the angle between them. After a further injection of local anæsthetic I cut down upon the horizontal needle and had no difficulty in touching and removing the glass splinter, in spite of the facts that its small size (about 1 × 1 × 5 mm.) and transparency made it invisible until it was actually removed, and that no tourniquet was used. The little operation occupied about ten minutes. This contrasts so markedly with the prolonged search one has so frequently had to make for comparatively large and visible foreign bodies and the necessary dissection among tendons, with proportionate risk of infection, that the somewhat lengthy procedure for localisation seems to me abundantly justified. It is true it merely transfers the labour and time from the operating theatre to the X ray room, but to the considerable advantage of the patient.

These few points—which it would be impertinent to suggest to the expert radiographer—may be of help to an amateur like myself. 1. While the position of the limb is of little or no importance, the long axis of the films should be exactly at right angles to the stereoscopic shift of the tube in order to obtain the maximum stereoscopic effect. 2. The stereoscopic shift should be parallel to one of the needles, preferably the one it is intended to cut down upon. This needle will then give the best impression of the depth and thus serve for localisation in two dimensions. 3. It is hardly necessary to add that the incision should be so placed as to lay bare only a portion of the "guide" needles in order that both may remain in their original positions until the foreign body is actually removed. 4. It is an immense advantage to be able to look at the stereoscope, after one is prepared for operating, immediately before making the incision.

I am, Sir, yours faithfully,

Martin Button, F.R.C.S. Eng. & Edin.

Rye, March 12th, 1926.

## A CLINIC OF MANIPULATIVE SURGERY.

*To the Editor of* The Lancet.

Sir,—I wish to make a preliminary announcement concerning a clinic of manipulative surgery instituted in London in response to many requests from medical men and others who feel that some such movement is urgently needed to endeavour to place the matter upon a scientific basis.

The clinic is primarily for the benefit of poorer patients in need of manipulative treatment, and the headquarters are at present at 59, Montagu-square, W. Treatment in the case of the necessitous poor will be gratuitous.

The clinic is held at present on Tuesdays between the hours of 2 and 6 p.m., and it is hoped when its activities are in full swing to arrange classes and demonstrations for practitioners and senior students, who are at all times welcome at the clinic. A scheme is also under consideration for the foundation of an institute for the scientific investigation and modern treatment of injuries and non-tuberculous diseases of joints, of which a further announcement will be made in due course.

I am, Sir, yours faithfully,

A. G. Timbrell Fisher.

59, Montagu-square, London, W. 1, March 22nd, 1926.

## THE MEDICAL REGISTER.

*To the Editor of* THE LANCET.

SIR,—I much regret to find that errors have crept into the figures which appear in Tables D and E in the Medical Register. These tables are now being reprinted, and will be issued in a corrected form to all those to whom official copies of the Register have been sent.—I am, Sir, yours faithfully,

NORMAN C. KING,
Registrar, General Medical Council.

44, Hallam-street, Portland-place, London, W. 1,
March 19th, 1926.

## THE FUNCTIONS OF THE SPLEEN.

*To the Editor of* THE LANCET.

SIR,—Your leading article last week, dealing with my two lectures on the Functions of the Spleen, naturally raises the question: Why did not the view put forward by Gray in 1854, that the spleen was a reservoir for blood, become thenceforward part of the body of accepted knowledge? The answer seems to be in Gray's complete failure to comprehend the mechanism by which this function was carried out. Gray denied that the spleen was contractile, and, as it seems to me, attributed a "connective" function to cells which are really unstriped muscle fibres. In justice to him it must be remembered that he lacked the now familiar methods of differential staining; acetic acid was his principal reagent.

Even if the spleen were not a muscular bag one could conceive of its performing the rôle of a reservoir of blood as the result of nice vasomotor adjustments of relative calibres of splenic artery and splenic vein. The decade between 1850 and 1860 saw, if my memory is correct, the dawn of our present conception of arterial blood pressure, as measured by exact kymographic methods, and also of the conception of vasomotor nerves. These ideas in 1854 were evidently not sufficiently advanced to illuminate Gray's philosophy.

I am, Sir, yours faithfully.

March 22nd, 1926. JOSEPH BARCROFT.

## MEDICAL DEFENCE UNION: A NEW BENEFIT.

*To the Editor of* THE LANCET.

SIR,—The Council of the Medical Defence Union has given careful consideration to the question of affording members of the Union protection when actions are brought against them in consequence of the acts of a locum tenens, who is not himself a member of the Union.

Recognising that a very considerable number of members are anxious to obtain protection in this respect, even if necessary at the cost of an additional premium, the Council has decided that in future it may at its discretion assume responsibility for any claim made upon a member in respect of the act or omission of any registered medical practitioner whilst temporarily employed as locum tenens for such member. In conferring this additional benefit of membership the Council has decided to require no extra payment beyond the ordinary annual subscription.

I am, Sir, yours faithfully,

HERBERT F. WATERHOUSE,
President.
JAMES NEAL,
General Secretary.

49, Bedford-square, London, W.C. 1, March 23rd, 1926.

---

DEATH OF DR. W. ARCHER.—Dr. William Archer, who died on March 1st, following a fall, was 50 years of age and was educated at Woodhouse Grove School, Apperley Bridge, and at the Mechanics' Institute at Leeds. He studied medicine at the Yorkshire College, now the University of Leeds, and qualified as L.S.A. Lond. in 1901. After this he worked as assistant in Leeds and at Huddersfield, and was for some years on the medical staff of the Menston Mental Hospital. Early in 1908 he settled in Earby and soon had a large practice. Although he took no part in public life, his private generosity was well known, and he had many friends. Dr. Archer leaves a widow.

# The Services.

## ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub.-Lt. R. A. Pallister to be Surg. Lt.

## ROYAL ARMY MEDICAL CORPS.

### TERRITORIAL ARMY.

Maj. (Prov.) R. O. Ward is confirmed in his rank.

J. Carver to be Lt.

Sanitary Companies.—Capt. A. Davidson resigns his commn. and retains his rank.

### TERRITORIAL ARMY RESERVE OF OFFICERS.

Sanitary Companies.—Capt. R. Cunningham, from the Active List, to be Capt.

## ROYAL AIR FORCE.

G. S. Strachan is granted a short service commission as a Flying Officer, for three years on the active list.

Group Capt. N. J. Roche is placed on the retired list at his own request (from half-pay).

## INDIAN MEDICAL SERVICE.

The King has approved the retirement of Col. T. B. Kelly and Lt.-Col. R. P. Wilson.

# Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

*Surgery.*—C. B. Ball, Sheffield; W. O. R. Fischer, Berlin and St. Thomas's Hosp.; W. H. D. Priest, King's Coll. Hosp.; and F. Widlake, Guy's Hosp.

*Medicine.*—W. O. R. Fischer, Berlin and St. Thomas's Hosp.; B. Horwitz, Guy's Hosp.; and E. J. Jones, Middlesex Hosp.

*Forensic Medicine.*—A. C. Hill, Liverpool; H. H. Lakin, Birmingham; I. Rivlin, Middlesex Hosp.; P. H. Row, London Hosp.; and G. H. Woeber, Glasgow and Middlesex Hosp.

*Midwifery.*—G. H. Bickmore, Charing Cross Hosp.; W. O. H. Evans, Bristol; C. F. L. Hassard, McGill; A. C. Hill, Liverpool; W. Johnson and R. D. Mason, St. Mary's Hosp.; and H. Rundstrom, St. George's Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: B. Horwitz, R. D. Mason, and G. H. Woeber.

INTERNATIONAL LIFE-SAVING.—Under the presidency of Dr. D. A. Coles, chairman of the British Council of the International Congress for Life-saving and First Aid to the Injured, to be held in Amsterdam from Sept. 7th to 11th next, a meeting was held in the Adams Hall of the Federation of Medical and Allied Services, 12, Stratford-place, London, W., on March 17th. The object of the Council is to harmonise the efforts of societies, firms, and individuals who are interested in life-saving and first aid, and the meeting was convened to help forward the arrangements for British representation in Amsterdam. Among those present were members of various Government departments, including Mr. F. H. Wynne, deputy chief inspector of mines, who has been commissioned by the Government as its representative, members of life-saving and first aid societies, including Mr. S. Osborne, who will represent the British Red Cross, Dr. G. Burnet, chief surgeon to the National Fire Brigade Association, who will represent that body, and Dr. M. L. Dobbie-Bateman, medical officer of Harrods Ltd. The Chairman, pointing out that the watchword of modern scientific medicine is prevention, said that while life-saving may be divided into preventive and curative methods, it might cost only a little care to prevent an accident, but to cure or replace the injured worker might cost hundreds of pounds. The accidents which caused the greatest loss of time and money were those attended with sepsis, and this sequela was generally preventable by cleanliness. It was here that welfare supervisors, whose appointment was, he said, so warmly supported by the Industrial Welfare Society, had proved pre-eminently useful. Mr. Wynne pointed out the economic value of the prevention of mining accidents, and Mr. F. W. Davy, representing the Federation of Medical and Allied Services, said that the Federation's constitution showed the fullest sympathy with the interests of industrial medicine. Mr. D. G. Monteith, speaking for the St. John Ambulance Association, pointed out the advantages of a knowledge of first aid. Mr. W. Henry, of the Royal Life-saving Society, pleaded for a greater active interest on the part of the British Government in congresses of this kind. Dr. Burnet said that the National

Fire Brigade Association would not rest satisfied until every individual fireman was proficient in first aid, and Mr. Osborne expressed the sympathy of the British Red Cross with the movement. Mr. Gaster, of the Illuminating Engineers Society, Dr. Dobbie-Bateman, and Mr. Humphries (Southern Railway) also addressed the meeting. The appointment of the executive committee was confirmed. This consists of Dr. Coles, Dr. Burnet, Colonel Pickard (Safety First Association), Mr. Monteith, and Mr. Osborne. It may be mentioned that the first International Congress of Life-saving was held in Frankfort in 1908, the second in Vienna in 1913, and the third, which should have been held in 1918 but was postponed owing to the war, will be held at Amsterdam this year. The fourth will be held in London, probably in 1928. Scenes purporting to be a wreck at sea and a railway accident will form the basis of practical work at the Amsterdam congress and the subjects for discussion and demonstration will include life-saving on board of air-craft and first-aid in the practice of sport. The hon. secretary of the British Council is Dr. H. S. N. Menko, 2, Grosvenor-gardens, Cricklewood, N.W. 2.

University of Manchester.—At a recent examination the Diploma in Psychological Medicine (Part I.) was conferred on R. B. F. McKail, M.B., Ch.B.

Dr. Robert A. Lyster has been elected president of the Association of County Medical Officers.

Naval Medical Compassionate Fund.—A meeting of the subscribers of this Fund will be held at 11.30 A.M., on April 23rd, at the Medical Department of the Navy, 68, Victoria-street, S.W., to elect six directors of the Fund.

Royal Navy Medical Club.—The annual dinner will take place this year at the Trocadero Restaurant, Piccadilly Circus, London, W., on Thursday, April 22nd, at 7.30 for 8 P.M. Members who wish to be present are asked to inform the hon. secretary at 68, Victoria-street, S.W. 1, not later than April 14th.

Mr. Henry Kimpton announces that he will publish the following books on or about April 1st: "The Principles and Practice of Endocrine Medicine," by Dr. W. N. Berkeley, of New York; "A Descriptive Atlas of Visceral Radiograms," by Mr. A. P. Bertwistle and Dr. E. W. Shenton; "A Handbook of Diseases of the Rectum," by Dr. L. J. Hirschman, of Detroit; and "Modern Methods of Amputation," by Dr. T. G. Orr, of the University of Kansas.

Metropolitan Asylums Board.—At a meeting of the Board on March 6th Dr. J. D. Rolleston and Dr. G. A. Borthwick were appointed medical superintendents in the Board's infectious hospitals service. Dr. Rolleston, who has been senior assistant medical officer at the Grove Hospital, Tooting, since February, 1921, becomes medical superintendent of the Board's Western Hospital. Dr. Borthwick, at present port medical officer and medical inspector of aliens in the health department, Plymouth, will be medical superintendent of the Northern Hospital, Winchmore Hill, in succession to Dr. C. E. Matthews, who will shortly retire.

Fellowship of Medicine and Post-Graduate Medical Association.—On Wednesday, March 31st, at 2 P.M., a special demonstration in clinical surgery will be given by Mr. A. Tudor Edwards at the Westminster Hospital. All members of the Fellowship of Medicine and its general course ticket-holders will be welcome. On Thursday, April 15th, a similar demonstration will be given by Mr. W. E. Tanner at the Prince of Wales's General Hospital, Tottenham. On Tuesday and Thursday, March 30th and April 1st, Dr. G. C. Low and Dr. P. H. Manson-Bahr will give lecture-demonstrations, illustrated by cases, at the London School of Hygiene and Tropical Medicine at 2 P.M. The following courses will be held during April: At St. Peter's Hospital, starting on April 19th and continuing for two weeks, a course consisting of clinical work in the hospital daily and special lectures; a series of four lecture-demonstrations on treatment by electro-therapy, by Dr. C. B. Heald at the Royal Free Hospital at 5.15 P.M. each Wednesday, beginning on April 14th; a special all-day course in proctology at St. Mark's Hospital from April 19th to 24th, including operations, lectures, lecture-demonstrations, and clinical work; a course in general medicine, surgery, and the specialties at the Bolingbroke Hospital, for two weeks starting April 19th; and a special two weeks' course in orthopædics at the Royal National Orthopædic Hospital from April 12th to 24th, when lecture-demonstrations will be given each morning preceded by operations, and the out-patient department will be open to post-graduates every afternoon. Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Royal College of Physicians of London.—The College will be closed from Friday, April 2nd, to Wednesday, April 7th, both days inclusive.

Moorfields Eye Hospital.—King Edward's Fund has approved the plans for a £10,000 extension; only 25 per cent. of the money has yet been obtained.

University of Sheffield.—Mr. H. Blacow Yates, F.R.C.S., has been appointed to a part-time demonstratorship in anatomy, and Mr. D. C. Harrison, Ph.D., to a lectureship in pharmacology.

Birth Control: Medical Aspects.—The Medical Committee of the National Birth-Rate Commission met on March 16th to begin an inquiry into all kinds of contraceptive methods and their effect on mind and body. The results of sexual abstinence, partial or complete, in married life, will also receive careful consideration. The members of the committee include Mr. Charles Gibbs, F.R.C.S. (chairman), Sir Arthur Newsholme (vice-chairman), Dr. Letitia Fairfield, Dr. Charles Porter, Dr. C. J. Bond, Dr. A. K. Chalmers, Dr. Agnes Dunnett, Miss Frances Ivens, M.S., Dr. Mary Scharlieb, Dr. Leonard Hill, Dr. Arthur Giles, and Prof. F. H. A. Marshall. The secretary is Rev. Sir James Marchant. The committee is sending out a questionnaire to gynæcologists throughout the country.

Courses at the Maudsley Hospital.—The following lectures and practical courses for a diploma of psychological medicine are to be given at the Maudsley Hospital, Denmark Hill, London, S.E. 5. Eight lectures on the Psychoneuroses, by Dr. Bernard Hart, on Mondays, at 3.30 and 5.30 P.M., from May 3rd; eight on Morbid Psychology, by Dr. Edward Mapother, on Tuesdays, at 2.30 and 4.30 P.M., from April 6th; four on the Pathology of Mental Diseases, including Brain Syphilis, by Sir Frederick Mott, on Fridays, at 2.30 P.M., from May 7th; two on the Legal Relationships of Insanity and Treatment, by Dr. C. H. Bond, on Tuesdays, June 1st and 8th, at 3 P.M.; eight on the Practical Aspect of Mental Deficiency, by Dr. F. C. Shrubsall, on Thursdays, at 2.30 P.M., from April 15th (transferring to Tuesdays in May); four on Crime and Insanity, by Dr. Norwood East, on Tuesdays, at 4.30 P.M., from May 4th; two on Abnormalities of the Fundus Oculi, by Mr. R. Foster Moore, on Wednesdays, May 5th and 12th, at 5.15 P.M.; three on Therapeutics, by Dr. A. W. Petrie, on Thursdays, at 4 P.M., from April 8th. There will also be six demonstrations in Clinical Psychiatry, by Dr. Mapother, on Wednesdays, at 2.30 P.M., from May 5th, and 12 clinical demonstrations in Neurology, six by Sir F. Mott, on Fridays in April and June, from April 9th, and six by Dr. F. L. Golla, on Thursdays, from May 6th, at 2.30 P.M. The fee for the whole course is 10 guineas; for one series of lectures, 2 guineas. In addition there is other opportunity for clinical experience at the hospital, and a limited number of vacancies for clinical assistants. Inquiries about lectures should be addressed to the Director of the Pathological Laboratory, Maudsley Hospital.

Operation on School-boy without Parent's Consent.—At an inquest held on a boy of 13 at Liverpool on March 10th it was stated that at a school inspection on Feb. 24th one of the medical officers had removed a small lump from the boy's chest. Making a diagnosis of molluscum contagiosum, he asked the boy whether he would like the lump taken away, and the boy agreed. The doctor then suggested that he should send for the boy's mother, but was told that she rarely left home. Accordingly he removed the lump without waiting for her consent. Later the boy complained of pains in the chest and was sent home from school. On the following day he died. The mother said that the lump had been on the chest since birth, and brought evidence to show that the operation had been done without proper aseptic precautions. The chief assistant medical officer of Liverpool elementary schools said that the doctor had exceeded his duty in operating on the child without consent; in his 20 years' experience this was the first case of a doctor performing an operation in school, and such a thing was against regulations. Prof. J. E. W. MacFall, who made a post-mortem examination, said that death was due to septicæmia, which had arisen from a septic healed cut on the boy's finger, and that the operation was not the cause of death, the wound on the chest being quite healthy. The boy's mother said that he had had the scratch on his finger for several weeks. The doctor who removed the lump admitted that he had not carried out the regulations of his department; he had acted, however, with a sole desire for the boy's welfare. The jury found that death was due to septicæmia resulting from the finger wound, and in no way connected with the operation. They recommended that no operation should be performed on a scholar without the parents' consent, and regret has been expressed on behalf of the education authority at this breach of its regulations.

Royal Society of Arts.—A Cantor lecture on Thermometry will be delivered by Mr. W. F. Higgins, M.Sc., of the National Physical Laboratory, on March 29th, at 8 P.M., at John-street, Adelphi, W.C.

Free Treatment at an Infirmary.—The board of the Ashton-under-Lyne District Infirmary is considering the appointment of an almoner to supervise admission to the wards. Many patients, it is stated, reap the benefits of charitable funds and the services of the honorary staff when they could well afford to pay for their treatment. The injured motorist and the victim of an accident, fully recompensed for all injury by an insurance company, are examples of those who should pay in full and without question the cost of their maintenance in hospital.

The late Dr. W. J. Barry.—Dr. William Joseph Barry, a well-known medical practitioner in South Wales, died at his residence in Penarth on March 18th. Born at Midleton, Co. Cork, in 1865, he qualified with the L.R.C.P., L.R.C.S. Glasg. in 1891, graduated M.D. Brux. in 1897, and obtained the F.R.C.P. Edin. in 1911. In the following year he took the M.D. degree of Durham University. Much of his earlier career was spent in foreign travel, but some 20 years ago he started medical practice in South Wales. He held appointments as hon. consulting physician to the Royal Hamadryad Seamen's Hospital, Cardiff, medical examiner to the Port of Cardiff for the Shipping Federation, and medical officer to the National Maritime Board for Cardiff. He was also a member of the medical board in connexion with the Welsh Ministry of Pensions at Cardiff.

Hospital Officers Congress.—The third annual congress of the Incorporated Association of Hospital Officers will be held on Friday, April 16th, at the Central Hall, Westminster. The delegates will be welcomed by the Mayor of Westminster and at 10.30 A.M. the congress will be formally opened by the President, Sir Arthur Stanley. At the morning session Miss R. E. Darbyshire, R.R.C., matron, University College Hospital, will read a paper on the Nursing Requirements of a Modern Hospital, and in the afternoon Mr. E. W. Morris, house governor, the London Hospital, will speak on the Geographical Distribution of Hospitals in Relation to Community Requirements. The social side of the congress will include a reception at the House of Commons, an official dinner to the delegates and their friends, and visits to London hospitals. Particulars from the hon. secretary to the Association, 28, Bedford-square, London, W.C. 1.

The Optical Convention, 1926.—This convention will be held from April 12th to 17th at the Imperial College of Science and Technology, Imperial Institute-road, South Kensington, London, S.W., under the presidency of the Astronomer Royal, Sir Frank Dyson, F.R.S. The object of the convention is to discuss British contributions to optics in recent years, and the industrial section of the exhibition will be confined to British manufactures. Communications on various scientific and technical subjects, including optical theory, optical history and education, optical glass and the manufacture of optical elements, astronomy, microscopy, spectroscopy and interferometry, photography, ophthalmology and spectacle manufacture, cinematography and projection, colour, photometry and illumination, surveying, including aerial surveying, optical apparatus in the fighting services have been promised, and popular lectures will be delivered. An exhibition is being arranged in three sections: (a) experimental and research, (b) historical, and (c) commercial. Applications for membership should be addressed to the Secretary at the offices of the convention, 1, Lowther-gardens, Exhibition-road, London, S.W. 7.

National Hospital, Queen-square.—At the annual general meeting of the Governors of the National Hospital for the Paralysed and Epileptic, Queen-square, held on March 23rd, it was announced that through a supplementary Royal Charter the name of the institution will be changed to "The National Hospital, Queen-square, for the relief and cure of diseases of the nervous system including paralysis and epilepsy." This step has been taken because the present title leads to the belief that the hospital is exclusively for paralysed and epileptic people. Moreover, patients suffering from other nervous diseases are deterred from coming owing to the fear associated with epilepsy, although only a small percentage of the patients are epileptic. In addition, people were inclined to gather from the old title the erroneous impression that the hospital is an institution for incurables.—A post-graduate course in Neurology will be held from May 3rd to June 25th. The course will include clinical lectures and demonstrations, teaching in the out-patient department, and pathological demonstrations. A course of lectures on the Anatomy and Physiology of the Nervous System will also be held if there are sufficient applicants. Further particulars may be obtained from the secretary of the hospital at Queen-square, W.C.

Yarmouth General Hospital.—At the annual meeting on Feb. 24th Dr. R. H. Shaw, the senior medical officer, pointed out that the staff is working under difficulties. The out-patient department is overcrowded, special departments are needed, and the structural deficiencies involve unnecessary expense. Perhaps in time, said Dr. Shaw, a new hospital could be put up.

Presentation to Dr. James Thomson.—On Friday, March 12th, Dr. James Thomson, of the royal and ancient burgh of Irvine, was entertained by his fellow practitioners and fellow townsmen to dinner at the King's Arms Hotel, and presented with a diamond ring as a mark of the esteem in which he is held. Dr. Thomson has practised for 40 years in Irvine, and intends to continue in practice there. Mrs. Thomson was presented with a silver tea service, and their daughter, Dr. Isabel Thomson, received a watch.

The late Dr. W. McAlister.—Born at Kilmarnock, Dr. William McAlister was the son of the late Dr. James McAlister, who long practised in that town. He was educated at Kilmarnock Academy and the University of Glasgow, where he graduated M.B., C.M. in 1879. Returning to help in his father's practice, he distinguished himself as an indefatigable worker devoted to his profession; in 1899 he took his M.D. at Glasgow University. Dr. McAlister held a number of local appointments; for 25 years he was surgeon to the Kilmarnock Infirmary, and for more than 10 years he acted as medical officer of health for the burgh. Amongst the schemes carried out under his régime was a maternity and child welfare centre, in which he took a keen interest; he also devoted much time and thought to the Kilmarnock Nursing Association. He was twice married and is survived by his wife, Dr. Jessie McAlister, who worked with him in his practice, and by a son of the first marriage.

Chelsea Clinical Society.—A meeting of this society was held at St. George's Hospital on Feb. 16th, when a discussion on the Endocrines was opened by Prof. Swale Vincent. The only instances of true substitution therapy at present, he said, were those of the thyroid and the pancreas, and perhaps of the ovary. Of these only one, the thyroid, was known for certain to produce any effects when given by the mouth. Many would include the parathyroid, though preparations of this gland were of no use when given by the mouth. Adrenin and posterior lobe pituitary were valuable as drugs, apart altogether from any question of substitution therapy, but neither of them had any effect when given orally. Dr. E. Bellingham Smith followed with an account of the clinical manifestations occurring when the ductless glands were at fault. Dr. F. J. McCann laid stress on the value of thyroid and calcium lactate in disorders of menstruation in the young. Especially were these drugs valuable in obese and anæmic subjects. Dr. H. A. Ellis reported good results with small doses of adrenin in the type of fatigue occurring about middle age, but was certain that only quite small doses of the drug should be administered.—Another meeting of the society was held at the Florence Restaurant on March 10th, when there was a discussion on Spa Treatment, to which Dr. Violle (Vittel), Dr. Dabidour (Mont d'Or), Dr. Forreyrolle (La Bourboule), Dr. W. Edgecombe, Dr. Argyll Campbell, Dr. M. B. Ray, and Dr. Lieven contributed. At both these meetings there was a good attendance.

Death of Dr. W. E. Haworth in Southern Rhodesia.—The London School of Hygiene and Tropical Medicine has received by cable the distressing news that Dr. W. E. Haworth has been killed in a motor accident in Southern Rhodesia. No details are yet to hand. It was only in August last that Dr. Haworth, who was then 60 years of age, entered with enthusiasm upon research work in medical entomology undertaken on behalf of the School, and interesting reports have been received from him showing with what energy and zeal he was throwing himself into the work. Not long before his last appointment Dr. Haworth was giving proof of his activity, remarkable for a man of his years, by scaling coconut palms at Dar-es-Salaam in the search for mosquito larvæ. The result of his researches at that time was embodied in a paper which appeared in the Transactions of the Royal Society of Tropical Medicine and Hygiene, and which was regarded as an interesting and important contribution to the literature on the subject. Dr. Haworth was the son of Robert Edmond Haworth, of Christchurch, New Zealand. He studied at Edinburgh University, took his M.B. and C.M. in 1892, and his B.Sc. in Public Health in 1893. From 1896–1917 he was in private practice in Southern Rhodesia, and was afterwards on active service with the Rhodesian native regiment in Nyasaland, German East Africa, and Portuguese East Africa. He held various Government appointments between 1920 and 1921, and devoted much time to observations on the breeding of mosquitoes in coconut palms. By his untimely death the London school has sustained a serious loss in the ranks of its research workers.

## NOTES ON CURRENT TOPICS.

### *Asylum Officers' Superannuation.*

Mr. TAYLOR presented in the House of Commons on Tuesday, March 23rd, the Asylum Officers' Superannuation (Amendment) Bill, a measure to amend the Asylum Officers' Superannuation Act, 1909, which was read a first time.

## HOUSE OF LORDS.

### THURSDAY, MARCH 18TH.

### *Coroners Bill.*

The House went into Committee on the Coroners Amendment Bill, the Earl of Donoughmore in the chair.

On the motion of Lord MARSHALL of CHIPSTEAD, an amendment was agreed to safeguarding the right of the Corporation of the City of London to appoint its own coroner, a privilege which they have possessed since the granting of a charter by Edward IV. It was explained that in default of a special provision in the Bill the right would pass to the London County Council.

The Bill passed through Committee and was reported to the House.

### TUESDAY, MARCH 23RD.

### *Smoke Abatement.*

Viscount GAGE (Lord in Waiting), in moving the second reading of the Public Health (Smoke Abatement) Bill, said that it was intended to follow the precedent of previous Bills on the subject, to extend the scope of certain Acts, and to encourage a more rigid enforcement of the existing laws. The first clause gave power to take proceedings irrespective of the colour of the smoke. It also defined the expression "smoke" as including soot, ash, grit, and gritty particles. The Bill also gave power to the local authorities to prescribe standards for the emission of smoke and to require that certain new buildings should be provided with arrangements for smokeless heating. The Minister of Health, he said, was anxious to reduce the volume of domestic smoke, which was responsible for at least 50 per cent. of the pollution of the atmosphere. Dwelling-houses would be exempt, because the installation of smokeless heating in them would not be compatible with the rapid and inexpensive provision of working-class houses, which were so urgently needed. People were exceedingly conservative in their domestic habits, and no cheap form of smokeless fuel was at present available for domestic consumption. Under clause 3, the Minister of Health, after a public inquiry and in consultation with the local authorities or other interests concerned, could make orders extending the list of noxious or offensive gasses mentioned in section 27 of the Alkali, &c., Works Regulation Act, 1906. Another clause exempted ships from the operation of the Bill. The measure would not bring about the complete disappearance of fogs or smoke which had such unpleasant and harmful effects, but the Minister of Health had gone as far as he could without adding to the cost of living and of production and manufacture.

Lord NEWTON said that the Bill, if amended in Committee, might do much good.

Earl DE LA WARR asked for an inquiry with a view to terminating the metallurgical exemptions contained in the Bill, and to enforcing model by-laws on local authorities.

Viscount NOVAR said he was disappointed that the Bill did not apply to Scotland.

The Marquess of SALISBURY (Lord Privy Seal) said he agreed that the need for the Bill was at least as great in Scotland as in England, but the law was not the same in the two countries. The Government had not overlooked the matter and intended to introduce a separate Bill for Scotland.

The Bill was read a second time.

## HOUSE OF COMMONS.

### TUESDAY, MARCH 16TH.

### GOVERNMENT ECONOMY BILL.

Continuing the debate on the second reading of the Economy (Miscellaneous Provisions) Bill reported in THE LANCET of last week,

Dr. DRUMMOND SHIELS said Scotland was very much interested in the Insurance Act. The population of Scotland as estimated down to the middle of 1925 was 4,891,300. One-third of these, or about 1,700,000, were in the Health Insurance scheme, two-thirds of that number being men and one-third women. No fewer than 28·3 per cent. of the population were resident within ten miles of the City of Glasgow, and 37 per cent. were in the four cities of Edinburgh, Glasgow, Dundee, and Aberdeen. On the other hand, the Highland counties covering 56·7 per cent. of the total area of Scotland had only 9·7 per cent. of the total population and had also a much reduced proportion of insured people. These conditions had added very greatly to the difficulty of the efficient administration of the Insurance Acts in Scotland. They also made the hospital problem of Scotland a very important one. A committee was appointed in June, 1924, to inquire into the state of the hospital services in Scotland and to make recommendations. That committee had recently reported as follows: "Our problem arises out of the fact that there are many persons in Scotland who, mainly because there are not enough hospital beds, are unable to get at the proper time the hospital treatment which they need. For all those persons the shortage of beds means a prolonging of their suffering; for some it means that treatment is delayed beyond the stage when effective treatment is possible; and for a few it may mean that they die before they can be admitted to hospital." The committee pointed out that even the waiting-lists did not give all who ought to be placed upon them. But as it was, in the six teaching hospitals of Scotland at the end of 1925 the waiting-lists were as follows: In the Royal Infirmary, Edinburgh, with 963 beds, there was a waiting-list of 2076; in the Royal Infirmary, Glasgow, with 665 beds, there was a waiting-list of 759: in the Western Infirmary, Glasgow, with 600 beds, there was a waiting-list of 1862; in the Victoria Infirmary, Glasgow, with 260 beds, the waiting-list was 450; at the Royal Infirmary, Dundee, with 441 beds, the waiting-list was 339; and at the Royal Infirmary, Aberdeen, with 327 beds, the waiting-list was 368. The total accommodation in these six Scottish hospitals was 3256 beds and there was a total waiting-list of 5851. Detailed recommendations were made of the number of additional beds required in each area, and the total new beds necessary in the opinion of the Committee was 3000. The committee made certain recommendations to help the voluntary hospitals to carry out a task beyond their own resources. One of those recommendations was a Treasury Grant of £900,000. Judging from the reception given to a similar recommendation by the English Hospitals Commission, the prospect of that grant being given was not very hopeful. The point he wished to make was that the committee found that about one-third of the beds in the Scottish hospitals were used for insured persons, and therefore one-third of the deficiency, amounting to about 1000 beds, was required for the needs of insured persons. This committee definitely recommended that a contribution to the voluntary hospitals should be made from the National Health Insurance Funds to help to solve the terribly serious problem of hospital accommodation in Scotland. Obviously, to get the specialist benefit required for certain cases and for other treatments of a complicated kind, the coöperation of the voluntary hospitals was required. It was only fair, then, that at least a contribution bearing a rough relation to the services rendered to insured persons should be made from Insurance Funds. Both on humanitarian and economic grounds the extension of medical benefits to specialist service and to institutional treatment was in the best interests of the country. It was just at this time when those various committees and commissions had shown how much all the money which the fund could produce under the present scale of contributions was needed, that the Chancellor of the Exchequer ruthlessly broke the bargain which had been made and destroyed all the hope of an extension of the services which were so much required by the insurance contributors of the country.

Mr. RHYS DAVIES said that he had endeavoured to make a calculation as to the amount which would actually be saved by the Government on the provisions relating to National Health Insurance. If those calculations were correct the estimated saving would be about £1,250,000. Each of the 15,000,000 insured persons would have taken away from him as from January, 1926, the sum of 5*s.* 6*d.* per annum. He would like to know if the Government was united on these proposals. He thought that he was right in saying that the approved societies would resist these proposals as far as lay in their power. A little over two years ago it was decided in agreement with the doctors that the medical benefit should be increased and the Government was compelled to find a sum of 3*s.* per insured member from some central fund. They took that amount from the Miscellaneous Receipts Account, derived in the main from proceeds connected with unclaimed stamps. He understood that that fund was now exhausted, and consequently the Government were now asking approved societies to shoulder the 3*s.* which was hitherto dealt with from the fund he had named. It would be interesting to find out the amount of money necessary to implement that agreement for 1921-25 in respect of the 3*s* because this Bill was retrospective. He thought it was grossly unfair to call upon the funds of the approved societies for the 3s. to which he had referred when the societies had had no say whatever in arriving at the agreement in connexion with that amount. Successive Governments had had great trouble with the panel doctors in this connexion. When the Act of 1911 was passing through the House the payment to panel doctors then proposed was at the rate of 4s. per insured person per annum. That sum had grown to 6s. 6d., to 7s. 6d., to 9s., to 11s., and now they were told that 13s. was required for medical benefit purposes.

Mr. SIDNEY WEBB asked if statutory obligations to creditors, pensioners, and public servants were more sacrosanct than obligations to the 15,000,000 insured contributors. It was perfectly true none of the benefits at present being paid would be diminished, but no one had had the candour to point out that if this Bill passed the benefits would be diminished in the future. Even existing benefits were rendered insecure by the cut which the Government was making.

The debate was adjourned until the following day.

### WEDNESDAY, MARCH 17TH.

#### *Economy Bill: Resumed Debate.*

The debate was resumed on the second reading of the Economy Bill.

Mr. LLOYD GEORGE said that Mr. Churchill had been beaten by the Admiralty, and that was why he was attacking Health and Unemployment Insurance and Education. There was no reason why they should spend all this money on cruisers which were not needed at all. A clear and definite bargain was made with the approved societies that if their funds accumulated they would be enabled to increase their benefits. That bargain to which the Chancellor of the Exchequer was a party was agreed to by the House of Commons, therefore it was made by the nation. Now the House of Commons was asked to go back upon it. The right hon. gentleman had not waited before taking action until the approved societies had examined the recommendations of the recent Royal Commission. The majority of the Royal Commission turned down every proposal that would involve an additional burden on the taxes; but they said that by means of the accumulated funds and the contributions which were now being paid the approved societies could grant additional medical benefits and additional sickness allowances. Additional benefits which had been dangled before contributors for years were now to be denied them at the very moment of realisation. And what *for?* In order to save a penny in the pound on the income-tax. It was a distinct breach of faith with the industrial classes and might do much mischief at the present time. The Chancellor of the Exchequer did not really save money by this transaction. The Bill simply threw the whole of the burden on the rates. The alternative to this Bill was for the Chancellor of the Exchequer to say to the Government that he would only find so much for armaments.

Mr. NEVILLE CHAMBERLAIN (*Minister of Health*) claimed that the Bill did not reduce the value of the benefits received by insured persons. The Bill did not touch the surpluses which were accumulated under the first valuation, which amounted to something *over* £17,000,000, and the benefits which had been decided on by the various societies as a result of that first valuation would still go on. It did not touch the surpluses which had been accumulated since the second valuation was completed up to Sept. 31st, 1925. What it did was to slow down as from Jan. 1st this year the accumulation of further surpluses in the funds of the approved societies. They were not going to throw any society into deficiency by reason of the diminution of the State grants, because there was a provision which was contemplated by the Royal Commission for using the contingency fund—the reserve suspense fund—for assisting weak societies. The benefits declared on the second valuation would be available up to the end of 1931, and the benefit which might have been declared on the third valuation would not have come into operation until after 1931, so that there was some little time before the slowing down would be felt. As to this being a breach of faith, he would impress on the House that, in the opinion of the Royal Commission, Parliament was free to make such changes, however drastic, as experience of the 1911 Act had shown were desirable. Altogether, since the scheme was started, extra contributions beyond those provided in the statute had been paid by the State amounting to upwards of £21,000,000. There had been nine amending Acts and the scheme had been altered in all kinds of ways. It was really absurd, therefore, to say that it was a breach of faith at this stage to make a fresh alteration because one did not happen to like it. The real thing the House had to consider was not whether the Government had broken a bargain, but whether what the Government now proposed to do was fair and justified on its merits. The House should ask themselves if the Government were not entitled to slow down the rate at which the societies would accumulate these surpluses in future when the taxpayer was so heavily burdened.

The second reading of the Bill was carried by 322 votes to 142—Government majority, 180.

The Bill was then committed to a committee of the whole House.

#### *Medical Officers in Colonial Service.*

Mr. FORREST asked the Secretary of State for the Colonies the present position of the differences between his department and the British Medical Association with regard to the conditions of employment of medical officers in the Colonial service, and more especially in East Africa.—Mr. AMERY replied: I received a deputation from the British Medical Association on March 5th. Correspondence with the Association is still proceeding.

#### *Danger of Open Dustcarts.*

Mr. CAMPBELL asked the Minister of Health how many local authorities employed open dustcarts at the present time; and whether he would consider making the use of automatic closing dustcarts obligatory on local authorities.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: On the first part of the question, my right hon. friend regrets that he has not the information. On the second part, he has no authority to make the use of such dustcarts obligatory, but local authorities are increasingly making use of improved vehicles.

### THURSDAY, MARCH 18TH.

#### *The Legitimacy Bill.*

Colonel DAY asked the Prime Minister whether the Legitimacy Bill was likely to be brought before the House this year.—Mr. BALDWIN replied: Yes, Sir. The Government desire, if possible, to pass the Bill into law this session.

#### *Tuberculin Tested Milk.*

Mr. ALFRED WILLIAMS asked the Minister of Health the number of pedigree dairy herds which were supplying Certified Grade A (tuberculin tested) milk at the present time; whether all animals in these herds had been tested for tuberculosis; and, if so, at what age calves had to be tested.—Mr. NEVILLE CHAMBERLAIN replied: There are approximately 200 herds producing Certified or Grade A (tuberculin tested) milk, but I have no information as to how many of these are pedigree herds. The cows in milk in these herds and all the animals which are in contact with them are required by the Milk (Special Designations) Order to be submitted to the tuberculin test. Calves are not usually kept in contact with these cows, and consequently there is no necessity for young stock to be tested until they are introduced for milking purposes. If in any case calves are kept in contact with the cows, they must be tested at the time of the general tests of the herd.

#### *Life Pensions to Nurses and Officers.*

Mr. ROBINSON asked the Minister of Pensions what was the number of life pensions in issue on Feb. 24th, 1926, to officers, nurses, and other ranks respectively, where the assessment was 20 per cent., 30 per cent., 40 per cent., 50 per cent., 60 per cent., 70 per cent., 80 per cent., 90 per cent., and 100 per cent.; and what proportion was due to wound or injury, and what proportion was due to disease.—Major G. C. TRYON replied: The approximate number of life pensions in payment to officers, nurses, and other ranks, at the end of February, 1926, were as follows:

*Table of Life Pensions to Officers, Nurses, and Other Ranks.*

| — | Per cent. | | | | | | | | | Total. |
|---|---|---|---|---|---|---|---|---|---|---|
| | 100 | 90 | 80 | 70 | 60 | 50 | 40 | 30 | 20 | |
| Officers .. .. | 1,220 | 50 | 425 | 675 | 850 | 1,550 | 1,300 | 2,300 | 4,160 | 12,420 |
| Nurses .. . | 56 | 1 | 1 | 2 | 7 | 13 | 10 | 32 | 63 | 185 |
| Other ranks .. .. | 10,200 | 2,030 | 6,600 | 13,000 | 20,700 | 32,100 | 28,400 | 60,350 | 90,000 | 265,000 |

The proportions due to wounds and injuries and to diseases were as follows :

| | *Wounds and Injuries.* | *Diseases.* |
|---|---|---|
| Officers.. .. .. | 64 per cent. .. | 36 per cent. |
| Nurses .. .. .. | 17 „ „ .. | 83 „ „ |
| Other ranks .. .. | 70 „ „ .. | 30 „ „ |

Miss WILKINSON asked the Minister of Pensions how many nurses had received pensions as a result of disabilities arising from war service; and how many had been refused such pensions—Major G. C. TRYON replied: Up to the end of February last awards had been made to 2542 nurses. The records of the Ministry do not enable me to give the information asked for in the latter part of the question.

### *Health Insurance in Wales.*

Mr. DAVID GRENFELL asked the Minister of Health whether he would consider setting up a consultative committee for Wales to correspond with the representative body which had been established in England in connexion with National Health Insurance administration.—Mr. NEVILLE CHAMBERLAIN replied: I am considering whether arrangements may not usefully be made for regular consultation on matters of sufficient importance with persons in Wales familiar with approved societies' work.

### *Unhealthy Refuse Dump at Greenford.*

Colonel DAY asked the Minister of Health if his attention had been drawn to the fact that a refuse dump, several acres in extent, at Greenford, Middlesex, was menacing the health of the inhabitants of this district; and would he take such action as would overcome the danger of infection during the coming summer months.—Mr. NEVILLE CHAMBERLAIN replied: I am aware of this dump. Recent inspections showed great improvement in the conditions, and there was no evidence that there was menace to health. I have, however, directed that another inspection shall be made.

### *National Health Insurance Report.*

Mr. RAMSDEN asked the Minister of Health whether he had now considered the recent report of the Royal Commission on National Health Insurance; and whether it was proposed to introduce legislation to give effect to any of the recommendations made in this report.—Mr. NEVILLE CHAMBERLAIN replied: I have made myself acquainted with the recommendations of the Royal Commission on National Health Insurance, but I have not yet been able to give them the detailed consideration which they require, and I am not, therefore, at present in a position to make any statement as to the introduction of legislation to give effect to all or any of the recommendations.

### *New Site for London University.*

Mr. HARRIS asked the President of the Board of Education whether the Government had come to any conclusion as to the site for the headquarters of the London University; and whether he could make any statement of policy, so that the necessary funds might be collected.—Mr. R. MCNEILL (Financial Secretary to the Treasury) replied: I am not at the moment in a position to make an announcement.

### *Defective Vision in Children.*

Sir GEORGE BERRY asked the President of the Board of Education if his attention had been drawn to the recent report of the Council of British Ophthalmologists on the education of children suffering from defective vision due to myopia and other causes; and whether he proposed to take any action with regard to the recommendations contained therein.—Lord E. PERCY replied: I have seen the report in question. Provision has already been made in various parts of the country for the education of partially blind children on the general lines recommended in the report, and I hope that this provision will be extended as circumstances permit.

## MONDAY, MARCH 22ND.

### MEDICAL SERVICES IN THE NAVY.

The House considered the Navy Estimates on Report.

Sir BERTRAM FALLE urged that an appeal board should be granted to officers and men who were invalided out of the Navy. It was an absolutely wicked thing that the doctor who first examined the man should be able to put him out of the service. Last year 53 officers were invalided from the Navy for tuberculosis alone, and of that number only five cases were attributable to service. Last year, also, 217 young men were invalided from the Navy, where the standard of physical efficiency was the highest of any for tuberculosis. Yet within the past few years these men had been passed in as absolutely fit. Again, of these, only three cases were said to be attributable to service. He did not ask for a naval medical board, but only for a civilian board. This concession would not cost the Admiralty as much as it did to throw these men out, and he hoped that the First Lord would give his attention to the matter.

Mr. AMMON said that there had been a considerable amount of criticism of the cost of the medical service in the Navy. The First Lord had promised to look into the matter, and he would be glad to know the result of his investigation. The complaint made was that, compared with other services, the charge per head was excessive. Had inquiries been made during the past year into the possibility of bringing the cost of the medical service within more reasonable limits? The First Lord should also give consideration to the suggestion that some economy could be effected by the pooling of the medical systems of the three services.

Mr. BRIDGEMAN (First Lord of the Admiralty) said that, as he understood Mr. Ammon's remark about medical services, it was that there should be more coöperation than existed at present. A great deal was being done in that direction. So far as hospitals were concerned, they were gradually trying to use the same hospitals for the other services as well as the Navy, sometimes abolishing the Navy one and using the other, and vice versa. In that way improvement was undoubtedly possible. He thought that there were many difficulties in the way of a common medical service for the three branches. He doubted very much if they could recruit a doctor if he did not know to which of the three services he might be sent.

Sir GERALD HOHLER said that there was an opportunity to try to effect economies by combining the medical services at Chatham. There was there the finest hospital in the country, and the Navy and the Army were together in the same town.

### *Operation on Liverpool Schoolboy.*

Sir JOHN PENNEFATHER asked the President of the Board of Education if his attention had been called to a case in Liverpool where a boy of 13 died three days after a school medical officer had performed an operation upon him in the school; if so, had he inquired, or would he inquire, whether the death of this boy could be attributed to the operation; and, in that case, whether his department assumed responsibility for the payment of proper compensation to the parents.—Lord E. PERCY replied: I am aware of the occurrence referred to, which I deeply deplore. At the coroner's inquest the jury, after hearing the medical evidence, found that the boy's death was due to septicæmia from a wound on the finger, and was in no way connected with the operation. The performance of this operation appears to have been a contravention of the local authority's instructions to their school medical officers and of the practice of the school medical service.

Mr. HAYES asked how far the responsibility of the local education authority went in respect of the operation performed on this child during the time that he was under the authority's control.—Lord E. PERCY replied that he did not know whether Mr. Hayes was referring to a legal or a moral responsibility. He could not give a legal opinion on the matter.—Mr. HAYES asked whether, if there was no legal responsibility, or even if there was, would it not be handsomer that this matter should be dealt with by an *ex gratia* grant? Would the noble lord inquire into it, to see if such a grant could not be made out of public funds?—Lord E. PERCY said that he had no power to make any grant. That was a matter for the local authority.—Mr. HAYES asked whether, although Lord E. Percy had no power to make any grant, he would do his utmost to make representations to the local authority. If representations were received from the noble lord he was sure the local authority would give consideration to them and act in a very generous manner if he allowed them to do so.—Lord E. PERCY said that he must leave the matter to the local authority who, he was sure, were impressed with its importance.—Mr. HAYES asked whether, in the event of the local education authority giving generous consideration to the matter, Lord E. Percy would approve of their policy, but the speaker said that that was a hypothetical question.

### *Insanitary Conditions in Poplar.*

Mr. LANSBURY asked the Minister of Health whether he was aware that a considerable number of families are living under unhealthy and insanitary conditions in the borough of Poplar; that during the past 25 years the public health authority for that borough had made repeated applications and representations to the London County Council, urging that action should be taken to put an end to this condition of affairs; that the inspectors of the Ministry of Health had condemned certain areas as unhealthy, the latest date on which this was done being Dec. 10th, 1924, and the areas thus condemned being Birchfield-street, Bromley, Dunbar Cottages, and Baker's Alley; and, in view of the failure of the London County Council to carry out its statutory duties, would he take such steps as were within his power to compel that authority to deal with those areas.—Sir KINGSLEY WOOD replied: My right hon. friend is aware of insanitary conditions in the borough of Poplar. The particular areas to which the hon. Member refers were included in an improvement scheme made by the London County Council which my right hon. friend confirmed. The County Council are taking steps to carry out the scheme, and I understand that considerable progress has been made in regard to the acquisition of the property in these areas.

*Birth and Death Rate in Bengal.*

Mr. SCURR asked the Under Secretary of State for India the birth-rate and death-rate for the province of Bengal during the years 1923 and 1924.—Earl WINTERTON replied: The registered birth-rate for 1923 was 20·9 per 1000, and the death-rate 25·5 per 1000. Figures for 1924 are not yet available.

*Juvenile Offenders and Psycho-Analysis.*

Captain FAIRFAX asked the Home Secretary on what grounds, and to what extent, he had sanctioned the practice of subjecting juvenile offenders to experimenters in psycho-analysis; and what precautions he was taking against any possible dangerous results.—Sir W. JOYNSON-HICKS replied: I have not sanctioned any such experiments, nor have I any intention of doing so. I may add that the question whether any further provision should be made for the medical examination of young offenders, which is a very different matter, is being considered by the committee now inquiring into the treatment of young offenders.

*Tuberculin Tested Milk.*

Mr. ALFRED WILLIAMS asked the Minister of Health whether, in the case of a breeding herd which was supplying Grade A (tuberculin tested) milk, young heifers and bulls which were not in contact with the milking cows had to be tested for tuberculosis.—Mr. NEVILLE CHAMBERLAIN replied: No, Sir.

TUESDAY, MARCH 23RD.

*Sales of Methylated Spirits.*

Mr. HARDIE asked the President of the Board of Trade if he could give the sales in the United Kingdom of methylated spirits and the prices for November last, and the sales and prices for January or February this year.—Mr. A. M. SAMUEL (Parliamentary Secretary to the Overseas Trade Dept.) replied: I have no information as to the sales of methylated spirits, but in November 750,000 proof gallons of spirits were delivered for methylation in the United Kingdom, in January 728,000 proof gallons, and in February 726,000 proof gallons. The wholesale price of industrial methylated spirit, 64 per cent. over-proof, was at the rate of 2*s.* 5*d.* per gallon, and that of mineralised methylated spirit of the same strength 3*s.* 8*d.* per gallon, throughout this period.

*Baker's Itch.*

Mr. HARLAND asked the Minister of Health whether he was aware of the prevalence in this country of the disease known as baker's itch; whether such disease was notifiable; and whether he had any evidence showing that this disease was due to the modern use of chemicals in the bleaching of flour.—Sir KINGSLEY WOOD replied: The answer to the first part of the question is in the affirmative. This disease, which is not notifiable, was investigated by the medical department of the Ministry of Health in 1922, and these investigations did not disclose any reasons why it should be made notifiable. The answer to the last part of the question is in the negative.

*Arsenic in Fruit.*

Colonel DAY asked the Minister of Health if his department had received representations from the Surbiton council with regard to fruit exposed for sale and found to contain arsenic; and what action was being taken in this regard.—Mr. NEVILLE CHAMBERLAIN replied: Yes, Sir, I have received representations from the district council. The present Imported Food Regulations enable port and riparian sanitary authorities to seize and destroy any imported food which is unfit for human consumption, and I do not think that it would be practicable to strengthen these regulations in any way short of imposing an absolute prohibition on the importation of apples, a measure which would not in my view be justified in the present circumstances. I take the opportunity of adding that I am not aware of any case in which an excessive quantity of arsenic has been found on home or Empire-grown apples.

INADEQUACY OF THE BIRMINGHAM HOSPITALS.—The annual report of Birmingham *General Hospital* recommends the establishment of contributory schemes throughout the district served by the hospital, the financial position of which is unsatisfactory. As soon as these schemes are in working order the governors purpose abolishing the ticket system. The annual meeting declared in favour of the preparation of a scheme for the "establishment and development of a hospital centre on a suitable site elsewhere than in the centre of the city." The Birmingham hospitals are admittedly entirely inadequate. They all have long waiting-lists, and it is estimated that at least 300 more beds are urgently needed. The out-patient departments are equally congested.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 13TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 212 (last week 190); scarlet fever, 1738; diphtheria, 1180; enteric fever, 43; pneumonia, 1257; puerperal fever, 57; cerebro-spinal fever, 8; acute poliomyelitis, 4; acute polio-encephalitis, 2; encephalitis lethargica, 45; continued fever, 1; dysentery, 7; ophthalmia neonatorum, 112. There were no cases of cholera, plague or typhus fever notified during the week.

*Deaths.*—In the aggregate of great towns, including London, there were 2 (1) deaths from enteric fever, 1 from small-pox, 119 (60) from measles, 9 (3) from scarlet fever, 52 (3) from whooping-cough, 51 (16) from diphtheria, 43 (12) from diarrhœa and enteritis under 2 years, and 88 (15) from influenza. The figures in parentheses are those for London itself. For the sixth time during the last eight weeks the deaths from measles exceed 100. The small-pox death was fully described in THE LANCET last week (p. 610).

# Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

## LECTURES, ADDRESSES, DEMONSTRATIONS &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, March 29th, to SATURDAY, April 3rd.—LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Endsleigh-gardens, N.W. Tuesday and Thursday, at 2 P.M., Dr. Low and Dr. Manson-Bahr will give special lecture-demonstrations illustrated by cases in hospital.—WESTMINSTER HOSPITAL, S.W. Special demonstration in Clinical Surgery on Wednesday at 2 P.M. by Mr. A. Tudor Edwards. Further information from the Secretary of the Fellowship of Medicine.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
TUESDAY, March 30th.—5 P.M., Sir Thomas Horder: *Endocarditis (last Lumleian Lecture).*

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn fields, W.C.
MONDAY, March 29th.—5 P.M., Mr. Shattock: Pathological Conditions of the Breast.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, April 1st.—4 P.M., Dr. Pearson: Marasmus.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.
TUESDAY, March 30th.—4.15 P.M., Dr. D. Dougal: Ectopic Pregnancy.

# Appointments.

*FORD, R. K., M.B., B.S. Lond.*, has been appointed Resident Medical Officer to the Fulwood Institution of the Preston Union.

STOBBS, J. A., M.B., B.S. Durh., Certifying Surgeon under the Factory and Workshop Acts for the Alston District of the County of Cumberland.

TENNENT, A., M.B., Ch.B. Otago, Resident Medical Officer, Freemasons Hospital and Nursing Home, Fulham-road, S.W.

WEBSTER, J. M., M.B., Ch.B. St. And., Resident Medical Officer, Chesterfield Workhouse and Infirmary.

Queen Charlotte's Maternity Hospital: NELKEN, G. J. V., B.S., M.R.C.S., L.R.C.P., Senior Resident Medical Officer; REID, J. K., M.B., Ch.B. Liverp., District Resident Medical Officer.

Salford Royal Hospital: ECCLESTON, C., M.B., Ch.B., and MALCOLM, A., M.B., Ch.B., House Surgeons; ROANTREE, W. B., M.B., Ch.B., B.A.O., House Physician.

University of Manchester: BLAIR, DAVID, M.D. Glasg., and CORMAC, H. D., M.B., M.S. Madras, D.P.M. Manch., Lecturers in Mental Diseases.

# Vacancies.

*For further information refer to the advertisement columns.*

*Alton, Hants, Lord Mayor Treloar Cripples' Hospital and College.*—Second Asst. Res. M.O. £300.

*Belgrave Hospital for Children, Clapham-road, S.W.*—H.P., H.S., and Asst. H.P. Each at rate of £100.

*Birmingham City Mental Hospitals.*—Asst. M.O. £350.

*Cambridge, Addenbrooke's Hospital.*—Cas. O., and Res. Anæsthetist. At rate of £130.

*Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.*—Hon. Asst. Out-patient Reg.

*Derbyshire Royal Infirmary, Derby.*—H.S. £200. Also Asst. H.S. and Cas. O. Each at rate of £150.

*Durham County Council.*—Dist. Tub. M.O. £600.

*Exminster, Devon Mental Hospital.*—Jun. M.O. £300.

*Finchley Urban District, Ante-Natal Clinic.*—Med. Practitioner required. 2 guineas per session.

*Hackney Hospital, 230, High-street, Homerton.*—Jun. Asst. M.O. £350.

*Hospital for Consumption and Diseases of the Chest, Brompton, S.W.*—H.P. for six months. £50.

*Hospital for Diseases of the Throat, Golden-square, W.*—Med. Reg.

*Hospital for Epilepsy and Paralysis, Maida Vale, W.*—Res. M.O. and H.P. At rate of £150 and £100 respectively.

*Hospital for Sick Children, Great Ormond-street, W.C.*—H.S., H.P., and Asst. Cas. O. £50 in each case.

*Hospital of St. John and St. Elizabeth, 40, Grove End-road, N.W.* Res. H.P. and H.S. At rate of £100 and £75 respectively.

*Inverness, Northern Infirmary.*—Jun. Med. Res. £100.

*Lambeth Hospital, Brook-street, S.E.*—Pathologist. £500.

*London Temperance Hospital, Hampstead-road, N.W.*—Surg. Reg. 40 guineas.

*Manchester, Ancoats Hospital.*—H.S. At rate of £100. Also Asst. M.O. in Ven. Clinic. £1 1s. per clinic.

*Manchester Children's Hospital and Northern Hospital for Women and Children.*—Pathologist. £400.

*Manchester Royal Infirmary, Roby-street.*—Res. M.O. Also Asst. M.O. At rate of £200 and £100 respectively.

*Miller General Hospital for South-East London, Greenwich-road, S.E.*—H.P., £125. Also Asst. in Out-patients' Dept. £150.

*Oxford, Radcliffe Infirmary and County Hospital.*—Hon. S., Hon. Asst. P., and Hon. Asst. S.

*Paddington Green Children's Hospital, W.*—H.P. and H.S. Each £150.

*Parish of St. John, Hampstead, New End Hospital.*—Sen. Res. Asst. M.O. £250.

*Prince of Wales's General Hospital, Tottenham, N.*—Two H.S.'s. and one H.P. At rate of £120. Also Jun. H.S. and Jun. H.P. At rate of £90.

*Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.*—Asst. Res. M.O. At rate of £80.

*Redhill, Surrey, Royal Earlswood Institution.*—Jun. Asst. M.O. £250.

*Royal Chest Hospital, City-road, E.C.*—Res. M.O. and H.P. At rate of £150 and £100 respectively.

*Royal National Orthopædic Hospital, 234, Great Portland-street, W.*—H.S. At rate of £150 Also Hon. Ophth. S. and Hon. Dental S.

*St. Bartholomew's Hospital, E.C.*—Rose Research Fellowship in Lymphadenoma. £600.

*St. Leonards-on-Sea, Buchanan Hospital.*—H.S. £150.

*St. Mary's Hospital for Women and Children, Plaistow, E.*—Asst. Res. M.O. At rate of £130.

*St. Stephen's Hospital, 369, Fulham-road, S.W.*—Third Asst. M.O. £300.

*Southport Infirmary.*—Hon. Asst. S.

*Sunderland Borough Mental Hospital, Ryhope.*—Asst. Med. Supt. £500.

*Swansea Hospital.*—H.S. £150.

*University of London, King's College for Women.*—Head of Dept. of Hygiene and Bacteriology, &c. £400.

*Wallasey, Victoria Central Hospital.*—Jun. H.S. £100.

*West Ham County Borough.*—Asst. M.O. £600.

*West London Hospital, Hammersmith-road, W.*—Hon. Med. Radiologist.

*Winchester, Royal Hampshire County Hospital.*—H.P. £150.

*Wrexham and East Denbighshire War Memorial Hospital.*—Sen. and Jun. H.S's. At rate of £120 and £80 respectively.

# Births, Marriages, and Deaths.

## BIRTHS.

Abrahams.—On March 21st, the wife of Dr. Adolphe Abrahams, of Brook-street, W., of a daughter.

Currie.—On March 10th, at Morningside, Torquay, the wife of Dr. Currie, of a son.

Ritchie.—On March 14th, at Douglas-crescent, Edinburgh, the wife of Dr. W. T. Ritchie, of a daughter.

## DEATHS.

Adams.—On March 20th, at Bussage, Brimscombe, Stroud, G. E. D'Arcy Adams, M.D., aged 79.

Armstrong.—On March 17th, at Inglemere, Enfield, Arthur James Mackenzie Armstrong, M.R.C.S., L.R.C.P. (late of Southgate).

Barry.—On March 18th, at Plymouth-road, Penarth, Glam., William Joseph Murphy Barry, M.D., F.R.C.P., aged 60 years.

Finlayson.—On March 19th, very suddenly, at his residence, Elson-road, Formby, Lancs, Harold Turner Finlayson, M.B., Ch.B., aged 36.

Gosling.—On March 16th, suddenly, at his residence, Fivelands, Moseley, Birmingham, Charles Edward Gosling, M.D., in his 74th year.

Hopkins.—On March 16th, at St. Matthew's-gardens, St. Leonards-on-Sea, Charles Leighton Hopkins, B.A., M.B. B.Ch. Camb., late Medical Superintendent, York City Mental Hospital.

Taylor.—On March 15th, after a brief illness, Inglis Taylor, M.B., F.R.C.S. Edin., of 22A, Cavendish-square, London, W.1.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## PUBLIC HEALTH IN PERSIA.

### 1914–24.

By A. R. Neligan, M.D. Lond., M.R.C.S., D.T.M. & H. Camb.,

PHYSICIAN TO H.M. LEGATION, TEHRAN; BRITISH REPRESENTATIVE ON THE PERSIAN SANITARY COUNCIL.

### Part II.*

### *Epidemic and Endemic Diseases.*

Persia's three long land frontiers run with those of countries liable to outbreaks of plague and cholera. In Iraq, for instance, the former disease is endemic. The ports on her seaboard in the Persian Gulf are in regular communication with Bombay and Karachi, where both diseases are endemic, and on the opposite shore of the Gulf, along the Arab coast, and perhaps in the interior, there are endemic plague centres. Russia and Trans-Caucasia are liable to cholera and typhus fever; Trans-Caspia, Turkestan, and the Astrakhan district to plague. Any account of Persia's epidemiological situation would, therefore, in view of the possibility of the country serving as a channel for the spread of disease to the west, lose in interest were outbreaks on her frontiers not mentioned.

In the following résumé of the appearances of plague and cholera during the years 1914 to 1924, names of places in Persia itself are printed in italics, of places in the neighbouring countries in ordinary type.

In this résumé it will be noted that all ship-borne cases removed to quarantine have been included. Further, that in spite of the regular appearance of plague on her frontiers, the name of only one place in Persia recurs with any frequency (Mohammerah), and that in the case of all other places where undoubted plague has appeared during the last 11 years the disease was imported, and, with a single exception to be noted below, *did not spread.* As regards Mohammerah, it used to be said that plague was always imported from Basra only 25 miles higher up the River Shatt Arab, with communications by land as well as by water. It has been suggested that plague is by now endemic in Mohammerah town, but the facts are, on the whole, against this supposition.

Abadan town, on the island of that name six miles down stream from Mohammerah, has, however, come to cause anxiety. The name appears in the years 1923 and 1924 only, and yet some 700 cases have occurred there. The explanation is that between 1909 and 1912 the Anglo-Persian Oil Company set up a refinery on the island, and that, instead of a few huts, there is now a considerable town and several villages, with a total population of some 50,000 souls. In the early days of the rush of native labour and shopkeepers to the island, huts and bazaars sprang up on no definite plan on land outside the Company's control, and on which it was not allowed to interfere. When, therefore, plague was imported into Mohammerah in 1923 and thence spread to Abadan there was a sharp epidemic. The Company has taken most energetic measures since then. Side by side with its elaborate medical service it has organised a very complete sanitary section with port medical officer and assistants, isolation hospital, quarantine station, and disinfecting plant. In 1924 the number of cases was reduced by more than half. Between April and July more than 12,000 rats were destroyed by catchers brought from India.[1] The Company has for nearly a year now been building steel and brick huts for its labourers, of whom there are more than 10,000, on a site well away from the native town. Drainage is a difficult problem where the subsoil water is found at 2 feet, but it is being solved by means of pumps. Further, a piped water-supply was completed in December, 1924. The River Bameshir has been tapped four miles away by a 16-inch pipe, and a 2,000,000 gallon reservoir has been made, which will deliver filtered and chlorinated water to stand-pipes in the workers' village. The Company has also planned a site for a new town, and the inhabitants of the old are being encouraged to remove to it. A piped water-supply has been led to this site also. Everything possible is, therefore, being done to keep out cholera as well as plague. The problem is not an easy one on account of the communications by land and by small craft on the river.

### *Plague in the Interior.*

The question naturally arises whether plague is ever likely to gain a footing on the Persian plateau. From the résumé it is clear that, during the 11 years under review, it did not spread from any of the points attacked in the low land along the shore of, and around the head of, the Gulf—the most

---

* Part I. appeared in The Lancet, March 20th, p. 635.

[1] The 1925 plague season has passed without a single case at either Mohammerah or Abadan, and only sporadic cases in Iraq.

*Plague.*

| 1923 | | |
| Jan. | Mesoptamia | Bagdad, Basra. |
| March | Persian Gulf | *Chahbar* |
| April to July | Persian Gulf | *Mohammerah* 71 cases, 45 deaths. |
| May to July | Persian Gulf | *Abadan*: 481 cases 409 deaths. |
| | Mesopotamia | Basra and Bagdad and intervening places: 708 cases 413 deaths. |
| Dec. | Persian Gulf | *Lingah* Four cases from Arab coast: removed to quarantine |
| 1924. | | |
| Jan. | Persian Gulf | Debai Bahrein Island. |
| | Mesopotamia | Bagdad Basra. |
| Feb | Russia | Astrakhan. |
| | Khuzistan Province | *Naseri*: Doubtful. |
| March | Persian Gulf | Bahrein Island |
| March to May | Persian Gulf | *Abadan* 223 cases. *Mohammerah*: 162 cases, 115 deaths. |
| April | Persian Gulf | *Kishm I.* imported. *Chahbar* Imported. *Geshut* Small village five miles from port of Ganaveh 17 cases, 14 deaths. Imported by pilgrims and labourers returning from Iraq by native craft. |
| May | Persian Gulf | *Bunder Abbas* 12 cases, 7 deaths: imported either in quarantine station or located by M.O. *Bushire*: One case quarantine station. *Lingah*: One case. |
| July 10th | | All ports of Persian Gulf declared free of plague. Disease practically at an end in Iraq |

threatened frontier, but also the best protected. Indeed, the country presents formidable natural obstacles to such spread. At the same time it has to be remembered that authorities have *described two plague* centres on the plateau, one in the mountains of Kurdistan (Tholozan), the other in Khorassan in North-East Persia. *They* have however, been quiescent for the last 50 years, nor have there been any cases at Enzeli or Rasht on the Caspian for a like period, nor in Khuzistan, to which province plague was brought from Mesopotamia in 1876. The mention of suspected cases near Kermanshah and in Khorassan (1921) arrests attention but there can be *no doubt that* the diagnosis was not correct.

Since the 'seventies plague has appeared in the interior twice. In 1904 in Laristan, imported *from Lingah* on the Gulf, an outbreak which quickly died out; in 1905 in Seistan, East Persia. The origin *of this* epidemic was obscure. It appeared among the lake-dwellers of the Helmund, and there was a good deal to be said for the ingenious theory of Captain Kelly, I.M.S., who suggested that wild duck (which are known to eat dead rats) brought infected fleas from Astrakhan, where plague was epidemic at the time, during their migration. The evidence given of an epidemic in 1912 in the Sheikh Jam district of Khorassan, and of the finding of a single infected marmot, was not, in the writer's opinion, satisfactory.

Then as to carriers. On the plateau there are no rats, but there are house and field mice and jerboas. In Khorassan there is a species of marmot allied to the Manchurian tarabagan, and called by the Russians by that name.[*] There are rats in the southern ports and on the Caspian. The writer believes that Persia's relative freedom from plague will continue, and that she is not likely to serve as a channel by which it may spread towards the west. The introduction of railways may, however, quite well alter matters. Pneumonic plague has been reported in Mesopotamia, a country which is likely to be linked up with the Persian railway system of the future, and to which several thousand Persian pilgrims go every year.

A significant incident occurred at Tehran in 1921. During the unloading of a motor lorry from Bagdad a rat was seen to jump out none the worse for its long journey.

*Cholera.*

| Oct. | Kermanshah | *Sowmar, Kasr Shirin, Quraitu* (all on Perso-Iraqi frontier): 11 suspected cases |
| 1924 | | |
| June 7 | Khuzistan | *Abadan* One case |
| | Mesopotamia | Sporadic cases. |
| August | Russia | Astrakhan. |

Cholera is a much more anxious problem for Persia than plague. As far as she herself is concerned it can be definitely stated *that* there are no endemic centres in the country. It is the threat of introduction from outside that has to be feared, for, once having gained a footing, it is impossible to arrest. Here, again, the Persian Gulf ports, in constant communication with Bombay and Karachi, cause anxiety, but the coast is well protected, as was shown in the section on Public Health Services. The outbreak at Abadan in 1923, which led to a severe epidemic in Iraq, was started by a ship-borne case. The heavy pilgrim traffic through

---

[*] This marmot has been identified at the Natural History Museum, South Kensington, as *Citellus fulvus parthianus.*

Kermanshah and Kasri Shirin to the Shiah Holy places in Iraq, makes the sanitary situation there extremely important. The last real epidemic of Asiatic cholera was introduced by pilgrims returning to Persia by this route (1904).

The sanitary situation in Russia, and the reluctance of its new rulers to declare the existence of epidemic disease, have been further causes of anxiety. It will be noted that most of the places named in the above résumé are in north Persia. The disease was in every case brought in from Russia, in (it is true) the troublous war period, when there was constant going to and fro of military detachments. The epidemics were of a singularly mild character. They meandered slowly from town to village and town along the caravan routes; lingered, perhaps, during a winter, and revived in the spring.

The epidemic of 1916 was an instance. It came in from Baku in September, 1915, through the port of Enzeli, and in May, 1916, began to spread slowly up the 250 miles of main road to Tehran. By September the villages west of and close to the capital were attacked, and on the 23rd it was reported from the small town of Shahzabdulazim, six miles due south. The disease had passed round the outside of a city of 230,000 souls. On the 27th four cases were notified in Tehran, and the diagnosis was confirmed bacteriologically by the writer. They had come from Shahzabdulazim before communications were cut.

The disease in southern and central Persia in 1917 and 1918 was due to spread from the north. It presented similar low virulence. It is interesting to speculate as to what would have been the military and political consequences of the epidemic in southern Russia in 1915 if it had been one of true Asiatic cholera.

*Typhus Fever and Relapsing Fever.*

Both these fevers are endemic in Persia, but during the last 11 years they have only once become epidemic. Ordinarily, the cases are few and far between. Thus, the writer spent ten years in the country before he saw a case of typhus; this, sadly enough, was his Russian colleague at Tehran, and a year later the latter's successor died of the same disease. Both were working among Russian soldiers. Cases were notified to the Sanitary Council as follows:—

| | | |
|---|---|---|
| 1914. | | |
| Jan. .. | Typhus fever .. | Hamadan (Jewish quarter). |
| Feb. .. | Typhus fever .. | Van. |
| 1917–18, winter of | Typhus and relapsing fevers | A widespread epidemic. |
| 1921. | | |
| Dec. .. | Typhus fever .. | Ardebil. |
| 1922. | | |
| Feb. .. | Typhus fever .. | Askabad. |
| April* .. | Typhus fever .. | Tehran (30 cases). |
| 1923. | | |
| April .. | Typhus fever .. | Astara. |
| June .. | Typhus fever .. | Meshed. |
| July* .. | Typhus fever .. | Tehran (7 cases). |
| July .. | Typhus fever .. | Daragez. |
| 1924. | | |
| Dec. .. | Relapsing fever | Tehran (11 cases).<br>Bakharz, Turbat-i-Shaikh, Iam, and Khaf districts and Khorassan province: A severe outbreak: nature not recognised until recrudescence in July, 1925. |

* To end of year.

The epidemic of 1917–18 followed two years of drought and famine. The poor were all heavily louse-infected.

A troublesome sequela of typhus fever, and one observed for two to three years after this epidemic, was necrosis of the rib cartilages

Much confusion was, and is still, caused when any attempts are made to collect mortality statistics, by the fact that Persians use the same name for both typhoid and typhus: *haspeh*, an Arabic word signifying "spotted." There are two separate words in Arabic: *motbegheh*, typhoid; and *mohregheh*, typhus.

As to relapsing fever, only three cases verified by the microscope had been brought to the writer's notice during the previous 12 years, and they were in such widely separated centres as Tehran, Isfahan, and Hamadan. The spirillum found during the big epidemic resembled that described by Obermeier. Salvarsan and its substitutes were the only remedies found effective. The writer has failed to trace a connexion between *argas persicus*, the "stranger biter" of the Persians, and the accepted form of relapsing fever. Cases of fever attributed to its bites, seen by him at Tehran, have, in several instances, proved to be malaria. He has produced spirillosis of fowls with specimens of the tick obtained from Mianeh, its historical home, but has failed to infect man.

*Influenza.*

Persia suffered severely in the pandemic of 1918–19.* Coming as it did after two years of scarcity and epidemics of typhus and relapsing fever, the disease caused a great number of deaths. Accurate figures were impossible to obtain, but estimates of the mortality in various towns ranged from 1 to 10 per cent. of the population, and in the country districts it was even higher. Those who had chronic malaria offered little resistance; thus a military post of Indian and Persian troops lost 31 per cent. of its strength, and another post lost 72 per cent. The effect of slow (caravan) and rapid (motor-car) methods of travelling on the rate of spread was marked. Since the epidemic there has been every autumn and winter a great number of cases of severe respiratory catarrh, especially affecting the trachea, and liable to pass on to bronchitis and pneumonia.

*Malaria.*

By far the most serious disease in Persia is malaria. It causes heavy mortality every year, and keeps the inhabitants of whole districts in a low physical condition, which makes them an easy prey to other infections, such as tuberculosis, pneumonia, or influenza. That this should be the case in the Caspian provinces (Gilan, Mazanderan, Astarabad) is not surprising. The Caspian Sea itself is 84 feet below sea-level. Along it there is a belt of rice, cotton, and marsh country varying from two to 40 miles in width, with dense forest. The forest climbs up the foothills of the Elburz range to the summer quarters, where the trees gradually thin out and finally the bare mountains of the Persian plateau are reached, running up to an average altitude of 10,000 feet. Great masses of clouds, carried by the prevailing north-west wind, are continually rolling up against this huge barrier to deposit their moisture. The rainfall is high, 50 to 60 inches. There are innumerable rivers, moderate temperatures, mist, perpetual dampness, and rank vegetation—in a word, all the conditions that go to make up a malarial country.

The people as a whole are anæmic and distressful looking. Their life would be an easy one were it not for the wild pig which destroy their crops. As it is their rice fields provide most of what they and their animals need; fuel can be had for the cutting, and food is cheap and abundant, including game, wild fowl, and fish. But for these aids to resistance one feels that long ago the clouds of mosquitoes would have been left the forests to themselves. In the summer quarters the writer found that 100 per cent. of the children under 10 years of age had enlarged spleens. It was the same in the low country. At Mahmoudabad, a beautiful spot on the coast, said to be a particularly healthy village and to be comparatively free from mosquitoes, 60 per cent. of the children in the school had enlarged spleens. The raised sleeping platform for the summer months is the only means of prevention in use. There are no doctors except in the few towns, and there is very little quinine. When used it is taken haphazard and stopped when the fever ceases. The writer intends to publish at a later date notes on the anopheline species found in the Kujur and Nur districts.

*Conditions on the Plateau.*

The Caspian provinces, however, form but a comparatively small part of Persia, and the short description of the great central plateau, where there is no rain between May and October, and the total fall is only 8 to 10 inches, would suggest comparative freedom from malaria. It is true that the central desert (Dashti Lut and Dashti Kavir) escapes, but everywhere else in the mountains and valleys and plains there are heavily infected districts, some as heavily infected as the provinces described above. Water storage and irrigation methods and the nature of the rivers provide the explanation. In towns such as Tehran every house and every garden has at least one tank for irrigation, domestic purposes, and religious ablutions. In addition, many houses have underground cisterns for storing drinking water, which are filled from surface channels. All these tanks and cisterns are so many breeding places for mosquitoes.

As regards the rivers on the plateau, most of them end in the desert, forming swamps. They are tapped by irrigation channels leading to the different villages in the district, and these give rise to secondary smaller swamps or collections of standing water. A notable instance in the Tehran province is the district of Shahriar, a very fertile region to the south-west of the town, which it supplies with corn, fruit, and vegetables. It is watered by a stream from the southern slopes of the Elburz. Of late years so many of the men have died that the villagers have petitioned the Government to do something for them. The problem is an engineering one, not of great difficulty, but for which there are no funds available. The big landowners are not far-seeing enough to take the matter up. A little quinine has been distributed, and much advice. There is a district named Khar to the south-east of Tehran, where a certain amount of rice is grown, and similar conditions prevail. The villagers are heavily infected and are sallow and lethargic, very different from the sturdy hillmen a few miles to the north.

It is the same everywhere on the plateau, in spite of its magnificent climate, and malarial centres may be found in varying degree of intensity, in the towns, in mountain valleys where suitable conditions hold, and in the plains where rivers debouch.

---

* Loc. cit.

In the north-east there is much malaria in the province of Khorassan. In the north-west, in the Urumiah district of the province of Azerbaijan, an interesting change has come about as a result of the war. I have it on the authority of Dr. Packard, of the American Presbyterian Mission, that until the Turks invaded Persia malaria was rather rare and of a benign type. Since then it has become much more common and pernicious forms are frequently seen. In the west (Kurdistan, Luristan, Kermanshah, and Hamadan provinces) there is much malaria. The Marivan district of Kurdistan, for instance, where rice is cultivated, is particularly bad. In Khuzistan malaria is severe in the low-lying country along the rivers; the towns of Ahwaz, Shuster, and Disful are, however, little affected. In the south the Gulf towns are heavily infected. Malarial districts are found in the central provinces of Isfahan, Yazd, and Kerman, and in Fars. In the east, in Seistan and Baluchistan, malaria is not prevalent.

### *Malaria in Tehran.*

In the Tehran district, 3000 to 5000 feet above sea-level, with which the writer is most familiar, it is safe to say that few Persians escape infection at one time or another. The climate is so good, however, that a considerable measure of resistance is established, and chronic forms are not nearly so common as this statement would suggest. There are, nevertheless, districts, villages, and gardens, where malaria is particularly severe; none of the inhabitants escape, and many develop cachexia. Moreover, the district is in constant communication with the Caspian provinces through caravans bringing rice, charcoal, and milk products. Fresh infections begin to appear in May, and there is a great increase in the number of new cases, as well as of relapses, which begins at the end of July and continues during August and September. The mean average temperatures for these three months are: 81·24°, 79·81°, and 72·95° F. There are also years when, as in 1922, there is a great increase in the number and severity of the cases. It has been noted that such epidemics go with higher air temperatures.

All the three forms of malaria occur, but quartan infection is not common. The rise in the number of cases in August and September is almost entirely due to subtertian infection. The parasite is frequently associated with the benign tertian form. Pernicious attacks are frequently seen among labourers and the poorer pilgrims in epidemic years, resulting in coma, jaundice, and hæmorrhages. Hæmoglobinuria is extremely rare however; the writer has seen only one case in 19 years. All the usual complications of acute cases are seen, including a dysenteric form.

Chronic and relapsing malaria has to be constantly borne in mind in diagnosing and treating the most varied ailments. All the patients say they have had malaria; some have had dysentery or chronic bowel complaints. Persians in the towns are constantly taking quinine, and this practice often renders the diagnosis of acute fevers difficult, especially in the case of enteric, which not infrequently has an abrupt onset with rigors.

Persian doctors use inadequate doses of quinine, and a patient is rarely treated after the temperature has fallen. The custom of waiting until the temperature drops to normal before giving quinine is widespread, and is disastrous in the case of continuous pernicious forms. Another class of patient from whom quinine is withheld are pregnant women. The most intense and rapidly fatal cases of anæmia are seen among them. Administration of quinine by injection is far too common, and, unfortunately, the injection is frequently badly made. Patients, however, think that there is special virtue in the syringe, and *injectioon* has become a Persian word.

### *The Problem of Prevention.*

The malaria problem is a huge and difficult one. Individual effort is lacking, and prophylactic measures are not being taken by the Government, even to the extent of making quinine easily and cheaply obtainable. Even in the large towns where malaria is almost entirely "man made" (in Tehran entirely so), little or nothing is done. Indeed, in the capital the municipality has distinguished itself by constructing a series of small tanks from which the streets are watered, and which serve as additional breeding-places.

Shortly after his arrival in Tehran in 1900, the writer proved the efficiency of gold fish as larvicides after experiments made in the garden of the British Legation. Gold fish and mosquito larvæ are completely incompatible; they have never been seen together. Domestic ducks have been found of some use in clearing tanks, but frogs of none. The practice of keeping gold fish in tanks has steadily spread since then, but it is a long way from having become universal. Unfortunately, the gold fish have their enemies too—cats which wait patiently on the edge of a tank for a rise and crows which swoop and carry off young fry. If, moreover, the outlets of tanks be not protected with a strainer, fish will escape and be lost when the water is changed. With a proper sanitary organisation, furnished with police powers, malaria could be stamped out in towns like Tehran, where the only natural mosquito breeding-places are rare temporary collections of water the result of occasional storms, and the rest are entirely artificial and easily controllable. Personal prophylaxis is confined to the use of nets by the better-to-do classes, and the irregular eating of quinine for all and every indisposition and febrile disturbance.

The British and British-Indian forces on service in western and north-western Persia in 1918 and 1919 suffered severely from malaria. Had the advice of local practitioners been sought in advance they would not have failed to urge the adoption of prophylactic measures.

The following species of anopheline mosquitoes have been found at Tehran: *A. maculipennis*, *A. plumbeus*, *A. bifurcatus*, *A. pyretophorus*. They are distributed in a curiously irregular way, and are much easier to find outside the city than in it. A certain room was found one summer to be harbouring large numbers of anopheles. All the possible near-by breeding-places were excluded, and at length a newly-formed hidden one was found where an occasional water channel disappeared under ground and had scoured out a pocket. The next summer, during a corresponding period of seven weeks, 185 culex and only three anopheles were caught in the same room. Culex larvæ have been found in the Elburz range north of the city at an altitude of 9000 feet.

### *Tuberculosis.*

That tuberculosis in all its forms is steadily increasing in Tehran, as well as in other towns, is a frequently expressed opinion. It is seen also in the villages as well as among wandering tribes. The reasons for this are: (1) Overcrowding in the towns. (2) Absence of ventilation in the houses. (3) The use of wadded quilts which are never washed and which go from one person to another. (4) Ignorance of methods of prophylaxis. So great is the dread of the disease that knowledge of their condition is kept as long as possible from the afflicted. (5) Underfeeding and malaria. (6) Late diagnosis. The Persian's resistance is small, and it is doubtful if he ever recovers in his own country from the pulmonary form. Bone and joint disease is very common in spite of the fact that milk is never drunk unboiled. There are no means of isolating "open" cases. The treatment of surgical tuberculosis is very far behind modern requirements and hospital accommodation is lacking. The dry air and abundant sunshine make the plateau an ideal place for heliotherapy.

### *Venereal Disease.*

Venereal disease is widespread among all classes. The following points only will be noted.

Though gonorrhœa is generally insufficiently treated, and chronic urethritis its usual sequel, stricture of the urethra is not at all common. Gonorrhœa is a cause of much sterility. Syphilis is, on the whole, of a mild type, and attacks the cardio-vascular system, the nervous system, and the skin with nothing like the same frequency as in Europe. Aneurysm is one of the rarest clinical conditions seen, and general paralysis is also very uncommon. Hereditary syphilis is curiously infrequent in face of the great amount of the acquired disease seen.

### *Small-pox.*

Small-pox is endemic in Persia. There have been no big outbreaks during the period under review, but prevalence has been reported from numerous scattered districts. In 1920, and again in 1922–23, reports of this nature were received. That the disease has greatly diminished in the districts served by the public vaccination service is certain, but unfortunately there are no statistics to support this statement. In Tehran during the last four years, 370 deaths from variola have been reported—not an excessive number in an Eastern city of some 230,000 inhabitants.

### *Leprosy.*

Leprosy occurs in the provinces of Khorassan, Azerbaijan, Gilan, Kermanshah, and Kurdistan. Little is done in the way of care beyond making the advanced cases live in villages by themselves, and that in the two first-named provinces only. There they cultivate the soil and receive an allowance of corn from the Government. Their families accompany them. The disease does not, however, appear to be increasing. There is only one leper village in the populous province of Azerbaijan, for instance, and it contains only some 35 cases, a number which remains fairly constant. Not all the lepers in the province are in it, however, for people in the early stages may be seen elsewhere. Nothing would appear to prevent lepers leaving their districts and moving about the country if so minded, and cases from distant parts, and not all of them in the early stages, have been seen in Tehran. Persia was represented at the International Conference on Leprosy held at Strassburg in 1923.

### *Other Infectious Diseases.*

*Amœbic dysentery* is endemic. The bacillary form (Flexner) occurs at Tehran and, no doubt, elsewhere. No epidemics have been reported in the period under review.

The *enteric group* of fevers is endemic, but does not cause as much illness among Persians as the sanitary conditions in which they live would suggest. They believe themselves to have acquired a considerable degree of immunity through long drinking of contaminated water, and it is a very reasonable supposition. Fifteen years ago enteric fever was common in the scattered European colonies. Now, as a result of efficient inoculation, it is rare. There is a spring and an autumn rise in the number of cases, but no severe outbreaks have been reported.

*Sprue* occurs in Persia. Foreigners, Europeans, and Americans provide most of the cases. Good results have been reported from treatment with calcium salts and parathyroid gland.

*Encephalitis Lethargica.*—The writer reported a case from Tehran in January, 1922, and since then has seen two other acute cases. A number of cases of "Parkinsonisme" in young adults have, however, been seen both at Tehran and Isfahan. They came almost altogether from the country districts between the two towns. Cases of epidemic hiccough were seen at Tehran during the winters of 1923 and 1924.

*Anthrax.*—Infection of the skin is very common, and every summer there are larger or smaller outbreaks, generally in the villages. It seems to be a singularly benign disease in Persians. A well-digger, with a huge pustule on his face, has been known to walk three miles a day to and from his work and attend hospital for his dressing on the way. Anthrax in animals will be noticed in a later section.

*Leishmaniasis.*—Leishmania tropica, called by Persians *salek*, the diminutive of *sal* (year), is very common in some districts and does not occur at all in others. In Tehran, for instance, it is rare to see a Persian who has not had it; in Tabriz it does not exist. There is no lack of sand-flies in either city. Infection generally takes place in the autumn. Street dogs in Tehran and other places are often seen with the ulcers of the disease on their faces, generally on the nose, lips, or eyelids. A case of general infection (canine kala-azar) was found by the writer at Tehran, but he has not seen a human case. Though Europeans living in the city of Tehran are not seldom infected with *salek*, the writer, during 19 years residence in the grounds of the British Legation, has had only one member of the staff to treat—this although the houses have no immunity from sand-flies nor the numerous dogs from *salek*. The dogs have, however, always been shut up, and their sores destroyed with the actual cautery as soon as their nature has been settled by a microscopic examination. The police have been encouraged to destroy street dogs with sores, but not officially or with invariable success. These points are mentioned merely on account of certain gaps in our knowledge of the ætiology of leishmaniasis.

*Trachoma.*—Trachoma is widespread and a great cause of suffering and blindness.

### *Epizootic Diseases.*

Persia has suffered severely of recent years from outbreaks of disease among flocks and herds.

*Cattle Plague and Anthrax.*—In 1919 there was a widespread outbreak of cattle plague, which was particularly severe in the Tehran district and in the province of Fars. The diagnosis was confirmed by English and Swedish veterinary surgeons. Captain Lawrence, R.A.V.S., on service in Iraq, was, at the request of the Persian Government, authorised to visit the Kermanshah, Hamadan, Kazvin, and Tehran districts. He made a report and detailed recommendations. Subsequently, severe outbreaks were reported as follows:—

| | | |
|---|---|---|
| 1920 .. | Cattle plague .. .. | Tehran, Khonsar, Kerman, Hamadan. |
| | Anthrax .. .. | Tehran. |
| 1921 .. | Anthrax .. .. | Tehran. |
| 1922 .. | Anthrax .. .. | Hamadan, Kurdistan, Dehkurd. |
| | Cattle plague .. .. | Mazanderan, Kermanshah. |
| 1923 .. | Cattle plague .. .. | Hamadan, Kurdistan, Tehran, Gulpaigan. |
| | Anthrax .. .. | Mazanderan. |
| 1924 .. | Cattle plague and anthrax killed thousands of animals in the Tehran, Hamadan, Isfahan, and Sultanabad districts. The losses to landlords and peasants were very heavy, and the autumn ploughing could not be done in places. | |

Persia is essentially an agricultural country, and each province is largely dependent on itself for its food-supply, on account of the high cost of transport. The problem as to how to deal with these ever-recurring epizootics has become most urgent, and it is rendered doubly difficult by lack of funds. The Pasteur Institute at Tehran has shown the efficacy of prophylactic inoculation against anthrax, but has not had the means for carrying it out on a really large scale. (In 1924, 60,000 inoculations were done in the Tehran neighbourhood, and 4000 army horses were protected.) In view of the country's financial difficulties, it would appear profitable for the great landowners to finance the Institute for this part of its work, but they have not done so. The Persian Government has now decided to engage a French veterinary surgeon, and has voted £6000 for starting a veterinary service and institute.

*Glanders* is common in Persia, especially in the cities. In Tehran, where there are cavalry regiments, hundreds of two-horse cabs and a horse tram service, to say nothing of privately-owned horses and thousands of transport mules and donkeys, little is done outside the army in the way of prophylaxis. The writer has seen several human cases, all rapidly fatal.

(*To be concluded.*)

## CORRIGENDUM.

*To the Editor of* THE LANCET.

SIR,—May I trouble you to correct a mistake in the notice *re* the Status Lymphaticus Investigation, printed in your issue of March 6th, p. 506, for which I supplied information. The interim report of the original investigation was published in the *Journal of Pathology and Bacteriology* for *January*, 1925, not April, 1925.

I am, Sir, yours faithfully,

W. HOWEL EVANS,
Secretary.

Liverpool, March 10th, 1926.

## ARSENIC IN APPLES.

To the current number of the *Analyst* a paper is contributed by Dr. H. E. Cox, public analyst for Hampstead, who examined apples which were the subject of recent prosecutions. He points out that Dr. Voelcker's experiments at Woburn have shown that vegetables grown in arsenic-contaminated soil do not contain arsenic and he also states that there is clear evidence that arsenic is not natural to apples. The presence of lead with arsenic in or on the apples is fairly conclusive evidence as to the source. Dr. Cox found that 48 hours after spraying the interior of the sprayed apples contained from 1·3 to 3·3 parts per million of arsenic. It is unlikely that rain would remove all the lead arsenate from the surface of apples, but it appears that washing and rubbing in 2 per cent. caustic soda solution would do so. In the discussion which followed the reading of this paper before the Society of Analysts, sympathy was expressed with English retailers, as well as some curiosity as to the law in America regulating the use and sale of poisons. Opinions as to the efficacy of washing were varied.

## IRRITATION THERAPY.

WE have received a long communication from Prof. Dollken of Leipzig entitled "Vaccineurin: a Neurotropic Remedy." The paper proposes to show that non-specific agents may irritate the cells of affected organs, and thus bring about a reactive inflammation mobilising the curative agents of Nature to restore the normal functions of the cell. The definite irritation bodies which have in practice proved efficient in this way as a remedial agent for certain affections are some colloidal metals, milk injections, typhoid vaccine (in its American use for arthritis), and turpentine. Prof. Dollken holds that a preparation now produced at the Serum Works of Saxony, Dresden, under the name of Vaccineurin is of powerful therapeutic efficiency in this way. He describes it as an "autolysate of bacillus prodigiosus and staphylococcus mixed in a definite ratio," and considers his theories to be confirmed by successes in a large number of cases treated—the manuscript mentions 100,000 cases yearly, but this may be an error of typing. The injection can be made either directly into the blood circulation—the cubital vein is suggested as the site—or given intramuscularly, when a dose of 1·5 c.cm. of the solution produces a hardly noticeable local reaction. The pain of a neuralgia will thus be moderately increased either in intensity or frequency for some hours, but after every succeeding injection the reaction grows, it is stated, less intense. The treatment is recommended for various forms of neuralgia, the primary cause being considered irrelevant, and details of a number of successful cases are appended to the paper. As the treatment appears not to be dangerous within the suggested dose, a trial might be made of the preparation, but in view of the suggestion of the small part which ætiology plays in the theories for its employment, the desirability becomes obvious that these theories should be discussed by expert pathologists. We do not gather that Prof. Dollken has submitted his views to any scientific medical jury.

# Lumleian Lectures
ON
# ENDOCARDITIS.

*The First Lumleian Lecture in 1926, delivered before the Royal College of Physicians of London on March 23rd,*

BY SIR THOMAS HORDER, BART., K.C.V.O., M.D., F.R.C.P. LOND.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

---

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—My first and pleasing duty is to thank you, Sir, and the Censors of the College, for the honour of my appointment to the post of Lumleian lecturer. The gratification which I feel is tempered by humility when I recollect the long line of distinguished Fellows who have held this lectureship, a line which includes the illustrious name of Harvey. A man of my temperament must needs be appalled by such knowledge, and though my mind is thrilled by the thought that the subject which I have chosen for these lectures is not distantly related to matters which the greatest of our Fellows illumined by the light of his genius, I tremble at another thought—my incapacity to prove myself worthy of your choice. Indeed, I am ready to acknowledge that at the close of these lectures even the most generous of my hearers may find it a difficult task to credit me with casting a glimmer into the darkness that hides so much of the subject-matter with which I propose to deal. I shall be satisfied if a few of my audience, still generously disposed, may feel helped by reconsideration of old facts, by a frank effort to discriminate between what we do, and what we do not, know, and by the exercise of some care in suggesting how the present gaps in our knowledge may perhaps be filled, whether by clinical observations or by laboratory research. I shall resist the vanity of trying to say all that can be said on so large a subject, rather contenting myself by selecting certain features which overlap with my personal experience and reflections.

It may be advanced that in these days, when more exact knowledge of the inflammatory changes taking place in the heart as the result of rheumatic infection has led us to the realisation that the lesion produced is a pancarditis rather than an endo- peri- or myocarditis, the subject of endocarditis has become one of secondary importance. But given this concept of the effect of the rheumatic virus upon the heart, there has arisen, pari passu with its recognition, a growing interest in another type of heart infection in which, as is generally admitted, the brunt of the invasion and of the interaction between the infecting agent and the tissues certainly comes upon the endocardium. I refer to that group of infections which is for the nonce termed "bacterial." Of the growing importance of this type of endocarditis, which, but for the objection of adding one more name to a nomenclature already overburdened, might justly be called in contra-distinction to the rheumatic type "endocarditis vera," we are all fully aware. I shall ask no indulgence for making it the main purpose of these lectures, nor for bearing it constantly in mind when dealing with other types of endocarditis, with one and all of which it has important relations.

I know of no classification of cases of endocarditis which is scientific and therefore none that is helpful. Nor do I propose to offer one. If it be true that to have overcome the desire to classify is to have attained a little wisdom, then, in this matter, I have attained a little. A mere recital of the known infecting agents causing a morbid condition is not a classification, and in the case of endocarditis such a recital must perforce at present find the cause of the majority of cases lacking. I propose to proceed without a classification. I shall deal first with endocarditis as it results from rheumatic and syphilitic infection. I shall then consider the influence upon the endocardium of certain factors which are not, so far as we can judge, microbic. I shall follow this by a statement of our present knowledge of so-called bacterial infections, and I shall conclude by considerations of pathogenesis, prognosis, and treatment.

### RHEUMATIC ENDOCARDITIS.

It was in the course of his Lumleian lectures in the year 1891 that Sturges preached the doctrine of rheumatic carditis. Sturges's subject was Heart Inflammation in Children, and he laid emphasis upon the fact that rheumatic heart affections in children were almost always both endocardial and pericardial. Although he noted the frequency with which the myocardium was also involved, he thought this occurred as the result of the pericardium having become adherent. This idea was probably a survival of the teaching current before this time and indeed still prevalent at the time of Sturges's lectures. In Fagge and Pye-Smith's excellent text-book, in the edition appearing three years prior to Sturges's reference, occur the words, "There is no true carditis as there is no true inflammation of the brain. The inflammations of the heart do not directly concern the muscle, but the covering and the lining membranes." When this was written careful histological examination of the myocardium in rheumatism had not been undertaken and, I might add, encephalitis was not prevalent.

It is significant of the slowness with which ideas, however lucidly stated, and however logically supported, gain permanent and practical acceptance in medicine, that the doctrine so ably advanced by Sturges, 32 years ago still requires, and receives, reiteration to-day. The growing conviction of clinicians that the heart was seriously involved as a whole, and from the first, in most severe cases of acute rheumatism, coincided with more critical investigation into the state of the heart wall in fatal cases; the discovery by Aschoff of the nodes which bear his name, and the confirmation of these and other changes by many histologists, put this conception of the unity of the cardiac inflammation in this disease upon a firm basis.

Norman Moore, the Lumleian lecturer in 1900, when treating of Rheumatic Fever and Valvular Disease, advanced the view that the endocarditis of acute rheumatism was the "central condition in the disease." According to Norman Moore, "endocarditis is always present" in acute rheumatism. "The conclusion to which I wish to attain," he says, "is that every case of rheumatic fever, whether the pains in the joints are slight or severe, is a case of endocarditis, and that the condition of the endocardium is not to be regarded as a frequent complication, but as the essential and invariable feature of the disease." Again, "If no evidence of endocarditis is to be found throughout an illness of which a symptom is arthritic pain, then that illness is not rheumatic fever, and the arthritis has some other cause." According to the view the various peripheral expressions of the rheumatic infection, such as arthritis, the cerebral symptoms, the lesions in the skin and subacute tissues, &c., are secondary to the heart affection. Whether he considered the mechanism by which these peripheral symptoms arose to be by a process of embolism or no Norman Moore did not say, but quite recently Krogius has taken this view, considering the symptoms in both acute rheumatism and in gonorrhœal rheumatism to be metastatic in nature. The alternative conception, of a virus which invades the blood stream and exercises a special affinity for heart muscle, serous membranes, subcutaneous tissues, skin, and certain parts of the brain, so that more or fewer of these structures are involved structurally and functionally at the same time seems rather more probable in the case of acute rheumatism.

Be the mechanism of the infection what it may, we have become satisfied concerning two points in relation to heart affections incident upon acute rheumatism: (1) That there is involvement of the heart in so great a proportion of the cases that it is wise to assume that it may be involved in all, and this even in the absence of any direct evidence by physical signs. (2) That the inflammation, especially in children, is of the nature of a carditis.

### *The Clinical Picture.*

Carey Coombs complains that the subject of rheumatic heart disease is still divided up in even the most recent text-books under all sorts of headings and is therefore only dealt with "in scraps" rather than as an entity, possessing a specific cause and presenting a clear clinical and pathological picture. This complaint seems reasonable and the great importance of the matter justifies the strenuous and repeated efforts of this author, as also those of Poynton, an earlier worker along similar lines, to get recognition of the facts as we now know them.

Of the other relations existing between acute rheumatism and endocarditis there is little or nothing to add to the facts as established many years ago. It is a little humiliating, for example, to read again the conclusions drawn by Church just 40 years ago from his examination of 700 cases of the disease, an analysis which is still quoted in the manuals. True, his estimate that only one half of the patients affected had some heart affection in their first attack has been considered too low, as seen by my reference to the views of his colleague Norman Moore, but Church's other conclusions have received confirmation down to the present day. For example, he said that the heart, when affected, is usually implicated during the first week of the attack; that the liability to cardiac involvement diminished with age; that no system of treatment, whether by drugs or otherwise, had, until then, been shown to influence the tendency to endocarditis in acute rheumatism; that relief from pain and fever occurred four or five days sooner in patients treated by salicylates than in those not so treated. It is doubtful if an analysis of the last 700 consecutive cases of acute rheumatism at the same hospital would lead to any different conclusions. Some things, however, which mere statistics could not show, would, I think, strike the thoughtful investigator if he took trouble to study individual records rather than merely to catalogue the main results. There seems little doubt that cases of severe acute endocarditis during the first attack of the disease are less common than formerly. Further, and perhaps explaining the fact, rheumatic fever in the severe form which was so common even 25 years ago, is not at all a common disease to-day. Is it not rather uncommon to see a young man, either in hospital or in private practice, presenting the picture of severe rheumatic fever? Yet such cases were an almost daily experience a generation ago. The hyperpyrexial form of the disease, and cases in which cerebral symptoms were a striking feature, seem entirely to have disappeared. Church, in the analysis just quoted, refers to the fact that already both pericarditis and lung complications had even at that time become much less frequent, and he adds with caution that it remained to be proved whether this was due to salicylate treatment or to other causes. After 40 years I fear that we must add that we still do not know. May it not have been even then due to some change in the interaction between the virus and the tissues resulting from a change in the virulence of the infecting agent? Or to some change in the resistance of the tissues infected? And may not the continued tendency, since Church's analysis was made, for pericarditis, and especially pericarditis with liquid effusion, to become less common, together with the lessened severity of the cases of acute endocarditis, and of rheumatic fever generally, be expressions of one or both of these same changes?

Following the line of thought introduced by Swift, who refers to two distinct types of response on the part of the tissues to infection by rheumatic fever—the proliferative and the exudative—we should say that the facts just mentioned suggest that exudative changes have become less common, whereas proliferative changes have remained as frequent as before, or have perhaps tended to increase in frequency. I shall refer again later to the relative infrequency of a first attack of acute rheumatic endocarditis in young adults. The possibility of a more complete resolution taking place in a valvulitis at this age, provided no further infection takes place, then in children, in whom the valve cusps are exceedingly thin and delicate, must not be overlooked.

But with this change in the character of the disease we call acute rheumatism or rheumatic fever, so that its more severe forms, and the coincident forms of acute endocarditis and pericardial effusion, have become much less common, there has probably occurred an increased frequency of the subacute and chronic forms of the infection, together with subacute and chronic endocarditis. I have not the benefit of a large experience at a children's hospital, yet I gather that this statement applies equally to children as to adults. It is constantly treated by those who see many ill children that rheumatic heart disease frequently arises in the absence of arthritic signs or indeed of any signs other than those indicative of the carditis. Although this fact was well known to physicians 40 years ago, the number of cases of rheumatic heart disease found in children who present no other feature seems now to bear a larger percentage to the whole than formerly.

### *Types of Resultant Lesions.*

Let me turn now to a consideration of the types of endocardial lesions which result from rheumatic infection, whether acute, subacute, or chronic. In the first place let me trace the course of a mitral endocarditis set up during an attack of rheumatic fever as closely as the known facts will allow. Since we must regard the inflammation as being essentially a valvulitis, a point emphasised by Swift in his recent studies, it is difficult to see how complete resolution can take place in so delicate a structure once it has been inflamed in the particular manner we know to be characteristic of rheumatism. It is probable, therefore, that few, if any, cases escape some degree of resultant injury. It is also probable that the conservative estimates of the earlier observers, such as Church, relative to the frequency of involvement of the heart valves in rheumatism, and also to the proportion of complete recoveries, is explained by the fact that the estimates were made at too short a period of observation after the attack. It was known that the systolic bruit, so frequently present during the attack, not infrequently disappeared for a time and then reappeared, but it is likely that many cases, and especially hospital cases, upon which almost entirely statistics are based, were registered as being free from valve mischief during this very interval when there were no signs of heart disease. Kemp, as the result of a careful analysis of cases of acute rheumatism in Radcliffe Infirmary, concludes that these older estimates of the incidence of heart affections and of subsequent damage were correct. He also concludes that much that was termed endocarditis in acute rheumatism was really myocarditis, and largely recoverable.

What were the recognised results of the valvulitis caused by acute rheumatism other than the hypothetical recoveries? They were three: (1) Cicatrisation takes place, leaving the valve cusps deformed and shrunken, but eventually settling down into permanent shape and remaining so for a long time, it may be many years, until some other factors come into play to disturb the compensating mechanism in the heart. To this condition the term "mitral incompetence" was given. (2) Further and frequent attacks of rheumatic infection may enhance the damage and increase the valvular defect. The resultant state of the mitral orifice imposes more difficulty upon the circulation, embarrassed further by associated changes in the mural endocardium, in the myocardium, and perhaps also in the pericardium, attendant upon the repeated invasions of the virus. The net result of this recurring type of acute rheumatism was the production of what was termed "double mitral disease." (3) The third alternative sequel was the gradual, or rarely the rapid, transition of the case into one of the ulcerating type of endocarditis. Of this sequence more anon.

### *Valvular Incompetence or Stenosis?*

What was the recognised result upon the mitral valve of rheumatic infection with more insidious and more chronic symptoms—"growing pains," mild chorea, myalgias, and various fibrositic manifestations? Although it was believed that any of the cases in this group might develop mitral incompetence with or without stenosis, there was a general belief that the net result was likely to be the production of mitral stenosis, with little or no regurgitation. I speak here of tendencies and of average results merely, not of absolute or universal findings. The more purely regurgitant a mitral lesion was found to be the more likely was it that the patient had had an acute attack of rheumatism and one attack only, or, if more than one attack, then with intervals of some years between the attacks. The more purely stenotic the mitral lesion was found to be, the more likely was it that the patient had never had an attack of acute rheumatism, but had had some mild rheumatic manifestations of the chronic kind just mentioned, or gave no history of any rheumatism at all. Looked at from another angle, the type case of mitral incompetence was an adult man who had had a severe but single attack of acute rheumatism in his teens. The type case of double mitral disease was a child or young adult, who owed the defect to repeated attacks of rheumatism, largely subacute, and who had considerable myocardial damage in addition. The type case of mitral stenosis was a middle-aged woman who rarely gave a history of acute rheumatism, and often gave no history of rheumatism at all.

How do these views compare with current ideas as to the resultant valve changes following rheumatic infection? There has been of late years a tendency to consider mitral incompetence a very uncommon sequel to acute rheumatism; indeed, many cardiologists of the present day have discarded the term altogether, or use it only to signify patency of the mitral orifice resulting from cardiac dilatation, temporary or permanent. When faced with a patient who presents signs of what others would term cardiac hypertrophy with a blowing systolic bruit transmitted to the axilla and a diastolic interval free from both bruit and thrill, they explain the state of affairs by postulating a diseased myocardium and a dilated mitral ring. And when dilatation of the heart arrives in such a case they read this to be due to failure of the myocardium originally and permanently damaged by rheumatism rather than due to inability of the hypertrophied ventricle to compensate further for the regurgitation. Others wander still further from the old conception, and, feeling so certain that the end-result of rheumatic mitral valvulitis is more or less of mitral stenosis, they actually apply this latter term to cases presenting the signs just mentioned. So the apparent anomaly arises, that of two physicians who examine the same case, one will label it "mitral incompetence" and another "mitral stenosis." All this is much to the confusion of the student's mind. Without, as yet, the help of proper figures to guide me, I think it is true to say that post-mortem experience favours the view that mitral incompetence due to old rheumatic endocarditis is much less common than it formerly was.

### *A Paradox.*

It is not so very important that such a paradox arises as it is that the circumstance denotes very definitely a changed conception in the rheumatic process. The change is far-reaching in its effect upon our attitude towards post-rheumatic hearts; it is only as yet partly reflected in the text-books and in the routine teaching of the schools. It is, I think, of more than academic interest to inquire if this change be due to more careful and more prolonged observations carried out upon hearts affected by rheumatism or to an actual change in the material observed. That our predecessors were not less skilled than we are with their hands and ears scarcely admits of doubt. And certainly they gave as much time to thought on all these matters. Moreover, be it noted, the particular point is not one upon which either X rays or instrumental methods have thrown much light. It is, however, possible that the opportunity for continued and prolonged observations upon large numbers of cases of heart disease has been greater during the post-war period.

I am as yet uncertain which of the two explanations I have offered for this change of attitude is the correct one, or whether it be each explanation in part. Auricular fibrillation has been the subject of so much attention of late years, and is so intimately bound up with heart failure in mitral stenosis, that there is possibly an added factor here in concentrating the mind upon this particular condition. Put briefly, the changed conception resolves itself into this—that very much of the life-history of the rheumatic heart may be expressed by the term "chronic rheumatic valvulitis." There certainly seems much reason in disallowing that the progressive sclerosis which goes on in the mitral cusps and adjacent endocardium, up to the production of the "button-hole" mitral orifice, is merely a slow residual contraction after an initial injury. That some chronic and persistent irritant is still at work through long periods of time seems certain. But is that irritant the rheumatic virus?

### *"Pure Stenosis."*

The occurrence of "pure mitral stenosis" in women who give no history of any illness prior to the development of cardiac symptoms has always been a puzzling fact. And remains so to-day. An analysis of the last 100 cases of pure mitral stenosis admitted to St. Bartholomew's Hospital shows that 76 were females and 24 were males. In 63 out of the 100 cases there was no history of acute rheumatism, and in 36 out of the 100 cases there was no history of rheumatism or of any allied condition. Of these 36 cases 27 were women and 9 were men. In a careful analysis of 50 cases of mitral stenosis in soldiers Cotton found a history of acute rheumatism in 22 only. French observers have considered that the condition is a congenital one—that is to say, that it begins as a congenital defect, and that this increases as time goes on. Dieulafoy, commenting upon the frequency of, and the unique features presented by, this form of valvular disease, says, "It is sometimes associated with congenital malformations" (but he does not cite instances of this). "It is independent of rheumatism and the other causes which usually give rise to endocarditis. This stenosis is associated sometimes with chlorosis." But we in Great Britain do not seem to have found this association any more than we have found Virchow's hypoplasia of the aorta in this connexion. There has been an effort made by other French observers to associate mitral stenosis with tuberculosis, not so much directly as indirectly, through tuberculous toxins. But this view, again, lacks confirmation. Poynton drew attention to the constancy with which renal sclerosis was found post mortem in association with these cases of advanced mitral stenosis, and it is interesting to reflect that it is in the same sex, and about the same age, that another mysterious sclerosing lesion appears in type form—namely, the so-called "contracting white kidney." Until we know more of the specific cause of rheumatism we do not seem likely to get nearer to the solution of the problem of this special form of mitral sclerosis. At present it is impossible either to assert or deny that these cases are the result of the specific action of the rheumatic virus. The fact that the specific histological lesion of rheumatism is not found in them certainly must not be taken as excluding the possibility of their being rheumatic, for the chronicity of the process and the fibroid nature of the changes in the valve segments would, by analogy with other chronic infections, explain this fact. We do not (readily) find gummatous formations in parasyphilitic diseases, nor tubercles in fibroid types of tuberculosis. Moreover, it is not easy always to demonstrate Aschoff's nodes in some cases of carditis in which, on all other grounds, we have no reasonable doubt that the infection is rheumatic. Whatever the ætiology of mitral stenosis in its extreme form in adults may be, it seems certain that the proportionate incidence of chronic sclerosing endocarditis is greater than it formerly was. It is tempting to associate this fact with that other fact to which I have referred—the decline in the incidence of severe acute rheumatism and a relative increase in mild and recurring cases.

Of the endocarditis occurring in scarlet fever I will only say this—that there seems to be a proportionately greater tendency for aortic involvement than in the case of acute rheumatism, a point to which I shall refer again.

### SYPHILITIC ENDOCARDITIS.

The affections of the endocardium due to syphilis are probably less difficult to define than in the case of rheumatism. We know that the part most often affected is that of the aortic cusps, and we also know that such affection is in most cases part of an aortitis. Syphilitic disease of the aortic cusps leaves these delicate structures fibrosed and contracted, leading to aortic incompetence and its various sequelæ. Rheumatism affects the mitral much more often than the aortic cusps, and probably affects the aortic cusps alone quite rarely. The converse is the case with syphilis. It is generally held that the mitral cusps are not affected at all by syphilis, but I have been struck by the not infrequent presence of a well-marked apical systolic bruit in cases of parasyphilitic disease of the central nervous system and in the absence of any history of rheumatism. The bruit has been musical in character in some cases, a feature which makes it unlikely that the murmur has been due to mere dilatation of the mitral ring. I am not here referring to cases in which aortic disease is present, and in which, therefore, there might be secondary changes at the mitral orifice.

We owe to Warthin a very complete investigation into the changes induced in the heart and aorta by syphilis. Warthin's studies make it clear that these changes are both diffuse and focal, and we cannot but be struck by the resemblance in many points between the mode of attack of syphilis and of rheumatism. In both infections there are produced proliferative lesions, largely perivascular in nature, with nodal structures which are recognisable histologically. There is some not distant resemblance between these nodal lesions in the two diseases, so that it is a little strange that the likeness between the Aschoff bodies in rheumatism and the small gummata in syphilis of the heart has not led oberwers to consider if the virus of acute rheumatism may not be spirochætal in nature. Warthin and others have pointed out that the *Treponema pallidum* is sometimes demonstrated in large numbers in the myocardium, even when there are none to be found elsewhere in the body. So far as the endocardium is concerned, the typical lesion of syphilis is undoubtedly a mesaortitis affecting chiefly the base of the aorta, which includes the sinuses of Valsalva, the roots of the aortic cusps, and the part of the aorta just above these structures. No doubt in many instances the process includes a true aortic valvulitis. The disease is prone to be very latent, so that our evidence of its actual incidence, in terms of frequency, can only be [illegible]irectly. The sources of this indirect evid[illegible]: (1) Patients occasionally come under observation with symptoms which render a diagnosis of syphilis of the aortic ring extremely probable, and they respond well to antisyphilitic treatment. I shall return to these later. (2) Aortic incompetence in men about the age of 40, who give no history of acute rheumatism or of any other infective process likely to cause endocarditis, and whose blood gives a positive complement-fixation test for syphilis, is quite common. We seem justified in regarding these cases as residual after old syphilitic disease of the aortic cusps, or, indeed, as being still the subjects of aortic syphilis. (3) In the post-mortem room we frequently come across undoubted evidence of syphilitic disease of this region of the aorta which has not been suspected during life. This may be because death has been sudden or because the actual damage to the aortic cusps has not been so severe or so prolonged as to lead to symptoms. The extreme latency which is so marked a feature in syphilitic disease of the aorta was strikingly illustrated in the case of a policeman admitted to St. Bartholomew's Hospital. His age was 32 years. His history was to the effect that whilst assisting a fellow constable to lift a corpse down a flight of stairs his companion, who went before, slipped on a step and fell. The patient, in order to save himself from falling also, leant back heavily, still holding on to the dead body. At the moment that he did this he felt a sharp pain in his chest and felt faint. He was assisted downstairs and to the open air, sat down, and soon felt better. However, he was sent home, and still feeling queer he went to bed. His wife, who was out at the time of his arrival, returned and brought him some tea. As he was taking this he saw his wife looking about the bedroom as though searching for something, and, on inquiring what it was, "I was looking for the cat," she replied. She then explained to him that she could hear the cat purring. However, no cat could be found, and the woman discovered, to her surprise, on approaching the bed more closely, that the purr proceeded from her husband's chest. The pain from which the patient at first suffered had gone completely in three or four days; he was kept in bed for ten days and then sent by ambulance to hospital. When seen, the bruit was still very loud and could be heard distinctly by leaning over the bed, it being not necessary for the observer's head to touch the chest wall. The murmur was highly musical in character and was diastolic in time. There was no evidence of cardiac hypertrophy, but there were the usual arterial signs of aortic regurgitation. A fairly marked anæmia was present and a "triple plus" Wassermann reaction. There was a history of syphilitic infection ten years previously. The patient improved rapidly under treatment by potassium iodide and mercury and left the hospital well but with the signs of aortic regurgitation. There can scarcely be much doubt that this was a case of rupture of an aortic cusp already the site of a syphilitic valvulitis.

### *Diagnosis.*

All this indirect evidence, taken together, makes it certain that syphilitic aortitis, with aortic valvulitis, is a not uncommon disease. It is obviously very important that we should bear this fact in mind in our practice and be prepared to suspect the disease, even though, as I shall now proceed to show, our means of diagnosing it with certainty are slender. If we wait until gross structural changes are produced in the aortic cusps we wait too long. It is to be doubted whether, in syphilis, as in acute rheumatism, complete resolution can ever take place once valvulitis has been present. But by checking, or by stopping altogether, the process of active infiltration and proliferation in the valve cusps we can lessen the residual damage in these structures, and thus prolong considerably the period of relative cardiac sufficiency which every case of aortic incompetence can only at best enjoy. No doubt a part of this increased freedom from undesirable sequelæ is due here, as it is in rheumatism in similar circumstances, to the fact that the myocardium has been protected from gross damage.

An important question arises: At about what interval after the primary infection does syphilitic disease of the aorta begin? At about what age shall we begin to consider the possible presence of the disease? In treating quite recently of a series of cases of cardiac syphilis, Carey Coombs computes that the period between infection and the onset of the symptoms was over 20 years; he gives the average age of his patients as 53. Coombs does not distinguish between the cases showing evidence of aortic disease and those whose main defect happened to be myocardial, and it may perhaps be assumed that such distinction would have affected these figures. As the result of a still larger number of cases studied by him, Strickland Goodall has recently put the period elapsing between the primary infection and the appearance of symptoms even higher than this. Although I am unable to give statistics, I am led to the view from my own experience that these figures give no true expression of the early cases of the disease. It is notoriously difficult to differentiate between the fibrotic residues of old inflammation and the lesions of still active disease; no more common problem arises in the post-mortem room than the proper interpretation of the changes frequently seen in the aorta. And no less difficulty arises in regard to the interpretation of symptoms during life: are they due to active disease or to atheromatous changes in the production of which syphilis is only one causative factor? If we follow the view that smouldering infection still remains in all cases in which there is to be obtained a positive complement-fixation test this makes it more, and not less, likely that the first invasion of the tissues by the *Treponema pallidum* takes place much earlier than signs or even symptoms show themselves.

Is it not probable that the known facts in regard to that other distinctive and equally common syphilitic arterial disease, cerebral arteritis, give us some guide in this connexion? Unless we have some reasons for taking a different view, it is at least likely that the time of incidence in the course of syphilis of arteritis in the branches of the circle of Willis approximates to the time of incidence of syphilis of the aorta and the aortic cusps. And the former we have fairly good evidence for placing at from five to ten years after the primary infection. The difference in the age-incidence, when calculated from a large series of cases, would be explained by the fact that syphilis of the cerebral arteries can scarcely remain long without symptoms, whereas syphilis of the aorta can and frequently does. Perhaps this matter may be stated most clearly by postulating two somewhat different types of lesion produced by syphilis in the aorta, as there are two somewhat different types of lesion in the central nervous system. There is an earlier lesion of the gummatous kind, largely proliferative in character, and possessed of focal lesions in a high degree, and a later type of lesion, largely fibrotic in its features, to which the term "parasyphilitic" may not be inappropriately applied. If this conception be admissible then the apparent discrepancy to which I have referred would be explained. So also would be explained, and rendered again analogous, the known lack of effective response to antisyphilitic treatment in cases of syphilitic aortitis when once the signs of aortic incompetence are present. No doubt both types of lesion may be present at the same time, a fact which accounts in part for the great difficulty often experienced in the interpretation of post-mortem findings. If this view be substantially correct, it becomes a still more urgent matter to track down the early cases by all means in our power. We must look for these cases in men (by preference) who are between the ages of 25 and 40.

### *Symptoms and Physical Signs.*

The main, and in perhaps most of the cases the only, symptom is pain, anginoid in character, situated in the region of the sternum, rather than in the region of the precordium, with a zone of reference or spread less extensive than is usual in angina pectoris. The pain is usually induced by, or increased with, effort, but this feature is not constant. Shortness of breath and the effort syndrome are sometimes present, but when this is so it is probable, from our general knowledge of these symptoms, that there is myocardial disease in addition to, or rather than, aortitis. There may be complaint of more general symptoms, such as slackness and vague dyspeptic symptoms, and the patient may be anæmic. But since these latter symptoms are common to so many diseases, it remains that it is the pain, and the pain alone, which arouses our suspicions in most of the cases.

As regards physical signs, these are absent or are equivocal. Lack of clearness in the aortic second sound, whether directly over the valve or at any point where the aortic second sound is listened to critically—and this should include the region just above the xiphisternum—is very suspicious. A ringing character to this sound, in the absence of high arterial tension, is perhaps equally significant. More change than one of these—to wit, a definite diastolic bruit—probably means that the valvulitis is not early and that resolution will not occur completely with treatment. I have only once, in a case of syphilitic aortitis, heard a definite diastolic bruit which disappeared with antisyphilitic treatment. It returned some two years later, despite continued treatment, and the patient then developed the arterial signs of aortic regurgitation. It is to be inferred that the disease was not detected at a sufficiently early stage to avert cicatricial changes. It is perhaps doubtful if we could ever completely avert some degree of cicatricial changes if a syphilitic valvulitis were once established, any more than we can in a rheumatic valvulitis, even though our means of treatment are much more "specific." The disappearance of the bruit and its reappearance later in permanent fashion is very reminiscent of what we know to happen not infrequently in the case of rheumatic fever.

I have never satisfied myself that the disease in its curable stage yields demonstrable dilatation of the aorta by physical signs. Nor have I ever got this evidence from X ray examination, though I understand that Price has met with a different experience. Our French colleagues construct a more elaborate picture of the signs and symptoms of early degrees of aortitis, but I find it difficult to follow them in actual practice. I doubt if at present we can go further than to say that a man below the age of 50, whose arterial tension is not raised, whose blood gives a positive complement fixation for syphilis, and who complains of pain that may reasonably be attributed to the aorta is probably suffering from syphilitic disease of this structure. If his age be under 40, the diagnosis is less uncertain. Treatment should be carried out promptly and thoroughly, and, since it is held strongly by some high authorities that active syphilitic infection should be presumed so long as the complement-fixation test remains positive, here, at least, this doctrine should determine our action, since there is so much to gain if it be true, and so little to lose if it be false. The important points are these: first, that it may be possible to detect and to treat syphilitic aortitis before as yet the aortic cusps are involved; and, secondly, that if it be detected and treated whilst as yet the degree of valvulitis is slight, the resultant valve damage may be so little and so unprogressive as not to prejudice the patient for an indefinite number of years.

### INFLUENCE OF CONGENITAL DEFECTS.

I pass now to consider certain ætiological factors in the production of endocarditis, both of the valve cusps and of the chambers of the heart, which, though the exclusion of a chronic infective element must only be presumed at any time with great caution, appear to be outside the sphere of microbic activity. Having spoken of the possibility of congenital defects in connexion with some cases of pure mitral stenosis I will take these first. It has been for a long time held that congenital defects in the heart are almost confined to the right side of this organ. Such defects as are found in the left side, if we except these gross defects which lead to such massive disturbances of the circulation that there are early and lethal results, have been too lightly passed over. There is good reason to believe that we have been too cavalier in our observations concerning the intimate anatomy of the heart valves, and of the aortic valve in particular, in relation to endocardial disease. Deviations from the normal in these delicate structures may well prove to be a determining factor in infection of a grade hitherto unsuspected. This possibility did not escape the eyes of older observers. Thayer reminds us that the recognition of the fact that bicuspid aortic and pulmonary valves predisposes to disease is as old as Paget. Osler also pointed out the liability of these malformed segments to sclerotic endocarditis. Of 17 cases examined by him, all presented sclerotic changes and the majority of them had, during life, the clinical features of incompetence.

Glynn, who gave the Lumleian lectures upon Infective Endocarditis in the year 1903, refers in detail to a specimen obtained from a man aged 48 years, in which one of the two cusps was found to be torn and everted and whose fatal illness started after a strain, during which it is presumed that the diseased cusp was damaged. I pointed out in 1909 that congenital defects that were compatible with good health and were outside the category of those grosser lesions which were to be recognised during life might still be of great importance in inducing active endocarditis. I cited cases of this as illustrated by defective interventricular septum and patent ductus arteriosus in patients of 31 and 42 years of age respectively. I drew special attention to the association of bicuspid aortic valves with bacterial endocarditis in 1905 when publishing the first case of endocarditis due to Pfeiffer's bacillus. In 1909 I dealt with this point more fully, having found bicuspid aortic valves in two other hearts in the museum of St. Bartholomew's Hospital, each the site of bacterial endocarditis. In still a fourth specimen, from a case of pneumococcal endocarditis, the pulmonary valve cusps were only two in number. Since that date four other hearts have been added to the museum, all showing bicuspid aortic valves, and all affected by bacterial endocarditis. In addition, Dr. T. H. G. Shore, the curator, possesses three unmounted specimens of a similar kind which he obtained from soldiers dying of this disease in France. It is very clear that the condition here dealt with is one of considerable importance.

In 1923 Lewis and Grant contributed a valuable paper to *Heart*, in which they treated of the normal structure of the aortic valve and especially of the relations of the aortic media to the annulus fibrosus. They describe in detail four cases of the condition of bicuspid aortic valve and seven further cases associated with bacterial endocarditis. There follows an analysis of 106 cases collected from the literature. Of these, 63 were males, 20 females, and in 23 cases the sex was not stated. These authors estimate that no fewer than 23 per cent. of males reaching adult life, and possessing congenitally bicuspid aortic valves, die of active endocarditis. The moral of all this is, as Libman remarks, that it behoves us to be much more critical than we have hitherto been in our examination of diseased hearts in the dead-house. Interpretations of our findings must needs be very cautious since the matter is by no means easy. We must endeavour to distinguish (*a*) true congenital defects, (*b*) the sclerotic residuas of effete infections by rheumatism, (*c*) the results of healed bacterial infection, and (*d*) sclerosis from purely mechanical causes. With so many possibilities before us, it is obvious that the task is full of difficulti[illegible] I shall return to this matter in dealing wit[illegible] [illegible]s relating to pathogenesis.

# Goulstonian Lectures

ON THE

# DEVELOPMENT OF PSYCHOPATHOLOGY

## AND ITS PLACE IN MEDICINE.

*Delivered at the Royal College of Physicians of London on March 11th, 16th, and 18th, 1926,*

BY BERNARD HART, M.D., F.R.C.P. LOND.,
PHYSICIAN IN PSYCHOLOGICAL MEDICINE, UNIVERSITY COLLEGE HOSPITAL.

## LECTURE II.*

IN the preceding lecture the development of psychopathology up to the formulation of the conception of suggestion was described, and an attempt was made to examine and evaluate this conception. We may now pass on to consider the history of a school of thought whose tenets are closely allied to those of the suggestionists. This is the so-called "persuasionist school," and its chief protagonists in the literature are Dubois, of Berne, and Dejerine, of Paris. Both are mainly concerned with therapy rather than with ætiology, and ætiology is with both authors regrettably vague and unsystematised, but they differ from one another in certain important respects. For Dubois[1] persuasion is a therapeutic process in which certain effects are produced by chains of logical reasoning, and he distinguishes it sharply from suggestion. He does not deny the potency of the latter, but believes it to be capable only of evil, and he ascribes to it most of the symptoms occurring in the neuropathic conditions which he treats. Persuasion, on the other hand, does not trade upon the blind credulity of the patient, but enables him to understand the erroneous lines along which his thoughts have proceeded and the way in which suggestions have produced an appearance of illness which is not really there, and it thereby gives him the necessary means to correct these morbid effects. Dubois's conception is almost entirely intellectualistic, and ascribes to reason a power as a driving force which it very certainly does not possess. It is an unquestionable fact that his method achieves results, but we are compelled to believe that this is because driving forces other than reason are interpolated, of which the suggestive potency of the physician's personality is probably the most frequent and important. In so far, however, as this suggestive action calls to its aid the patient's understanding, instead of merely dumping into his mind a belief without connexions or logical supports, persuasion may be said to be more integrative than simple suggestion, and to this extent superior to it.

Dejerine[2] is less intellectualistic than Dubois, and appreciates the weakness of reason as a driving force. His conception of persuasion includes not only the logical processes of Dubois, but also the principle that an "emotion" must be introduced in order to make these logical processes effective. He repudiates suggestion as a producer of evil almost as energetically as Dubois, but it is difficult to see how his conception of an emotional persuasion differs in its essentials from that of suggestion. His book is full of practically useful details of treatment, but his ætiological theories are not very precise. He ascribes a number of conditions to what he terms "preoccupation," citing, for example, the frequent functional disturbances of digestive and other organs which may arise from the patient becoming "preoccupied" with—i.e., having his attention fixed upon—the organ in question, and the consequent development

---

[2] Dejerine and Gauckler: The Psychoneuroses and their Treatment by Psychotherapy, English translation, 1913.

of fears and apprehensions, which ultimately produce the neurosis There can be no question that this conception of Dejerine's does apply to many cases, and that its application points the way to some valuable psychotherapeutic procedures If we examine the conception itself, however, it does not seem to be materially different from that of suggestion, and adds but little to the limited understanding of our cases which suggestion is already able to offer We may, indeed, sum up the whole contribution to psychopathology of the persuasionist schools as an elaboration of the suggestionist theories except in so far as these schools have to some extent become permeated by more basic conceptions taken over from other investigators whose methods of attack have been altogether distinct It is the work of these other investigators which has been chiefly responsible for the building of modern psychopathology, and to understand that building we must go back to the last decade of the nineteenth century and trace out the lines of development which diverged from the simple study of suggestion after the time of Charcot in particular the dissociation conception of Janet and the dynamic conception of Freud

The immensely important contribution of Janet may be said to have arisen from the blending of two fields of inquiry—the study of hypnotism on the one hand, and that of hysteria on the other hand, both of which had come within the purview of Janet's teacher, Charcot We have already dealt with the development of hypnotism, but something must now be said of the history of hysteria, and the views of that disorder which held the field at the time when Janet commenced his investigations

### THE HISTORY OF HYSTERIA.

In ancient medicine the phenomena of hysteria were explained by that demonological conception under which all pictures of disease were subsumed but this magico religious view seems to have clung longer to hysteria than to other disorders Its influence was rampant in the Middle Ages, when many hysterical symptoms were regarded as the characteristics of witchcraft, and others were believed to be the result of possession by benign or malignant spirits The first divergence from the demonological conception, however, is to be found in what may be called the metaphysiological speculations of the Greeks For Hippocrates hysteria was due to the wanderings of the uterus about the body in search of humidity, and the pressures thereby exerted upon other organs explained the various symptoms observed Coma and lethargy, for example, arose from pressure on the vessels mounting to the head, suffocation from pressure on the bronchial tubes, palpitations from pressure on the heart, and epigastric oppression from pressure on the liver Galen rejected the Hippocratic theory on the very solid ground that the anatomical fixations of the uterus did not permit of it wandering about the body but he substituted for it the scarcely better founded view that hysteria was the result of engorgement of the uterus by its own fluid or by menstrual blood Except for the demonological interlude of the Middle Ages, this uterine pathology persisted in various guises down to the seventeenth century, when Lepois,[3] in France, and Thomas Willis,[4] in this country, first put forward the conception that the seat of hysteria was in the brain The views of Willis are of interest to us here because he observed the causal relationship existing between emotional disturbances and hysteria, but he held that the former acted upon the brain by way of the "animal spirits," which, with the other writers of his time, he regarded as the moving force of nervous action, and therefore his view is essentially physiological and not psychological Sydenham[5] held that hysteria was a general malady of the nervous system, but here again he supposed this to consist in a disorder of the part producing "animal spirits"

The history of hysteria before Charcot may be said to have culminated in the work of Briquet, who in his "Traité de l'Hystérie," published in 1859, reviewed all the theories which had hitherto been put forward, and tested them in the light of his own observations Briquet's methods were admirably conceived, and they constitute perhaps the first clear attempt to apply to this sphere the rigid procedure of science He constantly emphasises the importance of unbiased observations of facts and the avoidance of a priori theories, and strives to base his own views entirely on the careful examination of his 430 cases He finally concludes that "hysteria is a malady consisting in a neurosis of the portion of the brain destined to receive the affective impressions and the sensations"[6] It will be noted that, although this definition contains some psychological terms, it is essentially conceived in a physiological spirit, and is pathological rather than psychopathological This view may be said, indeed, to have persisted as the doctrine of "functional nervous disorder" which held the field until comparatively recent times

Charcot noted that in certain cases of traumatic hysteria the physical accident was not in itself the cause of the illness, but that a part was played by the memories left by the accident, and finally he proposed the view that certain of the symptoms of hysteria were due to "ideas" With this view was laid the foundation-stone of the psychopathological conception of hysteria, and here also we see the beginning of a delimitation of "psychogenic" from other diseases. Charcot himself, however, did not follow out his observation to its logical consequences, but strove constantly to bring hysteria into line with organic nervous disorder He related its phenomena to those of hypnosis, and observed the effect of suggestion in both, but he regarded hysteria as a definite disease characterised by definite stigmata. He arrived, indeed, at a conception which was the converse of the later one of Babinski in that he held hypnosis to be a manifestation of hysteria, and therefore to be part of a disease in which suggestibility appeared, but did not constitute its essence

Nevertheless, the seed which Charcot had sown fell upon fertile ground, and was developed into a rich harvest by the researches of Janet.[7] He found that the phenomena of hysteria were capable of being interpreted in psychological terms, and he finally succeeded in formulating psychopathological conceptions which served, at any rate in some measure, to explain those phenomena The nature and importance of these conceptions will be best understood if a brief description is given of Janet's observations and conclusions with regard to a single group of hysterical symptoms, and for this purpose the familiar anaesthesias may be selected

In the first place, Janet noted that hysterical anaesthesia frequently had a peculiar distribution The well known glove anaesthesia, for example, ending in a sharp line at the level of the wrist, had a distribution which did not correspond to any possible lesion of the nervous system, but which did correspond precisely to something—namely, the patient's idea of his own hand Clearly, therefore, the incidence of this symptom was determined by a factor of a psychological order, and if this were so, it would be profitable to seek for a psychological conception in order to explain it Again, these anaesthesias exhibited features of a curiously paradoxical character It was observed that patients suffering from extensive hysterical anaesthesias involving large areas of the body rarely sustained any accidental injury, whereas patients with far smaller anaesthesias of organic origin, such as occur, for example, in syringomyelia, frequently sustained such injury. The only conclusion possible would seem to be that the patients must feel with their anæsthetic limbs, as otherwise injury would inevitably befall them. Similarly, it was found that patients with an extreme hysterical amblyopia, which reduced the field of vision almost to a single point, were able to play at ball, a performance obviously out of the question unless the major part of the retina were functioning normally. This paradoxical character appeared most clearly, perhaps, in the case of a boy who developed hysterical symptoms after being concerned in a fire. The symptoms were of two kinds: firstly, the presence of an amblyopia, which cut down the field of vision in both eyes to 30°; secondly, the occurrence of fits, which were originated whenever the patient saw a burning object. Now if the boy were tested with a perimeter in the usual way he was unable to see the paper disc until it had reached the 30° radius. Nevertheless, if a lighted match were substituted for the paper disc, a fit invariably occurred as soon as the match reached the limit of normal vision. Obviously, therefore, the patient could see over the whole field of vision, and equally obviously he was blind to everything outside 30°.

### DISSOCIATION OF CONSCIOUSNESS.

In order to explain these features Janet devised the conception of "dissociation of consciousness." He assumed that consciousness, instead of pursuing its course as a unitary stream, could be split into two or more independent currents, so that the consciousness of one current would be unaware of, and uncontrollable by, the consciousness of other contemporaneous currents. Some approximation to this situation occurs normally when we carry out at the same time two independent activities, such as playing the piano and thinking out some problem, but in hysteria the dissociation may reach an extreme degree. Here the sensations arising from an entire limb may be diverted into a current separated from the main stream of consciousness, thereby producing an anæsthesia. Although thus cut off, and incapable of being perceived by the main stream, they can influence the motor apparatus, and thereby determine the phenomena observed—the avoidance of injury by the anæsthetic patient, and the fits in the blind boy. In this way the apparent paradox, that the sensations exist and yet do not exist, can be resolved. The conception of dissociation, therefore, explains the observed facts, but if it is to satisfy the canons of scientific method it must also be capable of verification by an appeal to experience. Actually it does satisfy this further test because, if a method be devised whereby access to the dissociated portion can be obtained, the continued existence of the apparently absent sensations can be experimentally demonstrated. By using the manœuvre known as automatic writing, for example, the anæsthetic arm can be made to record, unknown to the patient, the fact that it is being pricked.

Functional paralyses are similarly explicable, as is also hysterical amnesia. The latter consists in a loss of memory for a certain defined period of the patient's life, extending over days, months, or years, and was a common phenomenon in the psychoneuroses of the war. Here, again, the conception of dissociation presumes that the missing memories are not destroyed but diverted into a current split off from the main stream of consciousness, and once more the validity of this conception can be experimentally demonstrated by hypnotising the patient, and thus recovering the lost memories.

Other hysterical phenomena, such as somnambulism and double personalities, can be explained by a dissociation essentially identical with that responsible for amnesias, but differing in its mode of incidence. In these cases a dissociated current suddenly usurps the field of consciousness, causing a complete break in [illegible] uity of the patient's experience and [illegible] After occupying the stage for a certain period of time the dissociated current is once more submerged, and the patient resumes the thread of his former life, generally without any awareness that it has been interrupted. Hysterical somnambulisms can be closely paralleled by certain conditions artificially produced under hypnosis, and a number of the processes occurring in hypnosis, particularly in its more profound phases, are to be interpreted in terms of dissociation.

The conception of dissociation cast a flood of light on a mass of phenomena which had hitherto baffled all attempts at explanation. It was legitimately constructed according to the canons of science by the careful collection of observed facts and the devising of a formula which would resume those facts. It could, moreover, be tested to any desired extent by constantly comparing the results capable of being deduced from the formula with those actually found by experience and experiment. Finally, it pointed out a road along which therapeutic attempts might hopefully be prosecuted. Certain difficulties have been noted in the application of the concept to some of the phenomena with which it is concerned, but these are due rather to misapprehension of the nature of the concept than to defects in the concept itself. For example, in many cases of hypnotic somnambulism the hypnotic consciousness is aware of the whole range of the patient's experience, whereas what we may call the normal consciousness has no knowledge of the experience belonging to the hypnotic consciousness. At first sight this one-sided and non-reciprocal lack of awareness may seem difficult to explain by dissociation, which would appear necessarily to involve a break between the two streams of consciousness equally untraversable in whichever direction it might be attempted, whereas in the example cited the break is impassable when viewed from the side of the normal consciousness, but traversable with ease when viewed from the side of the hypnotic consciousness. The difficulty is dependent, however, upon a misconception of the nature of dissociation, and an abuse of the spatial metaphor in which it is defined. Dissociation does not, of course, imply an actual separation in space, and from the nature of the phenomena with which it is concerned it obviously can have no real spatial significance whatever. Spatial terms are used because they afford a useful method of describing relationship, but actually the dissociation is a functional dissociation, an "out of gear" relationship, and if this is understood the existence of a non-reciprocal dissociation ceases to be inexplicable.

### THE SUBCONSCIOUS.

Janet's conception of dissociation involves necessarily another conception concerning which something must be said, that of the "subconscious." This term has been used in a variety of senses by different authors, but in Janet's work it indicates the existence, contemporaneously with the main stream of consciousness, of mental processes which are independent of and unconnected with the main stream. In this sense it will be apparent that subconsciousness is merely a corollary of dissociation, for a mental process which exists independently of the main stream of consciousness is a dissociated mental process.

The conception of the subconscious has been attacked on the ground that processes which are not part of the personal consciousness are not conscious at all, that they are merely neurological or physiological, and have no psychological aspect. This criticism arises from a complete misunderstanding of the nature and justification of a psychological conception. In the first place, the evidence for the existence of Janet's subconscious processes is precisely the same as the evidence for the existence of any conscious processes whatever. Both are dependent upon inferences from observed facts. If I see my neighbour writing certain words I infer the existence in him of certain conscious processes, but I have no direct experience of the latter; the only objective facts are the words and the actions I see. Similarly, if a patient's arm writes a coherent and relevant statement, although the patient himself has no knowledge of the fact that his arm is so engaged, or of the subject upon which it writes, I have as much right to attribute consciousness to the mechanism responsible for the statement written by the arm as I have to attribute consciousness to any other aspect of the patient's behaviour.[8] Secondly, the observed facts are not in themselves either physiological or psychological; they are behaviour facts, and the physiological or psychological aspect is only introduced when an attempt is made to devise conceptions to explain them. If explanation is attempted in terms of nerve cells and fibres a physiological conception is employed, if in terms of ideas and memories a psychological conception is employed. It is not that either conception is wrong; both are permissible, and the choice between them on scientific grounds depends entirely upon their relative utility in enabling us to resume and control the facts of experience. To object, therefore, that the facts which Janet interprets by his conception of the subconscious are physiological, and not psychological, is irrelevant and indeed meaningless. The only question at issue is whether in the present state of our knowledge a psychological conception, such as Janet's, permits us to understand, to predict, and to control the facts of hysteria and hypnotism better than a physiological conception. To this question there can only be one answer, although we are quite entitled to hope that ultimately a physiological explanation still more adequate and useful will be devised.

Morton Prince has explored the field opened up by Janet in several interesting directions, and has applied the concept of dissociation to the study of a wide range of phenomena. He has, indeed, used the experimental method in psychopathology more consistently than any other investigator, and his work is a valuable object-lesson of what can be accomplished by this method. In particular his fascinating "Dissociation of a Personality"[9] provides a convincing demonstration of the light which the conception of dissociation is able to throw on the problem of double personality, although, as we shall see later, it also affords an excellent example of the limitations of that conception.

Janet has himself extended the conception of dissociation to a wider field than that of hysteria and hypnosis He brought into a single disease-entity, under the name of "psychasthenia," practically all the manifestations of the psychoneuroses other than the definitely hysterical. In its symptomatology were included phobias, obsessions, compulsive actions of all kinds, morbid anxiety, and states of doubt and hesitation. This remarkable generalisation gathered together a multitude of syndromes which had hitherto been described as independent disorders under such names as "folie de doute," agoraphobia, and so forth, and conceived them all to be merely different aspects of one and the same essential disturbance The essential disturbance consisted in a dissociation analogous to that responsible for hysteria, although differing from the latter in certain important respects. Starting from the assumption that normal adaptation to reality requires the integration of a number of relevant mental processes, Janet held that both hysteria and psychasthenia are due to a failure of this necessary integration owing to the presence of dissociation. In the case of hysteria the dissociation is molar—that is to say, masses of processes are entirely split off from the main stream—thus producing the anæsthesias, paralyses, and somnambulisms. In the case of psychasthenia, on the other hand, the dissociation is molecular, the various processes not being completely segregated from one another but merely loosened in their interconnections, so that the firm integration required for efficient adaptation to reality cannot be obtained. In Janet's "Les Obsessions et la Psychasthénie" this principle is worked out in an extraordinarily ingenious manner, and it cannot be denied that it has some value as an explanatory concept. Nevertheless, although it gives us a measure of help and understanding in this complex and difficult field, there is little doubt that the conception of molecular dissociation is unduly wide, and describes a process so elementary and universal that it brings together diverse clinical pictures between which only a superficial resemblance can be traced. We see here, as we have already seen in the case of suggestion, that besetting tendency to generalise a valuable conception until its explanatory value becomes seriously impaired.

### THE PLACE OF DISSOCIATION IN PSYCHOPATHOLOGY.

We may now pause to consider the place in psychopathology of the conception of dissociation. Even in the wide sense which has just been discussed it has a certain value in that it emphasises the important principle that the processes composing mental activity are not uniformly bound together into a single stream, but may possess varying degrees of independence, a principle which gives us some understanding not only of psychasthenia, but also of the hallucinations, delusions, and other phenomena met with in the psychoses. It has been said, however, that this principle is so general in its application that it does not give much help in the interpretation of individual pictures of disease, and dissociation will therefore be a more valuable concept if it is limited to the original sense in which Janet brought it forward to explain the symptoms of hysteria.

There is no necessity to recapitulate the merits of this conception and the light that it has shed on the understanding and control of certain phenomena. Something must be said, however, concerning its limitations and defects. To begin with, it does not seem to be applicable to all the phenomena which occur in hysteria. It explains the anæsthesias, for example, but hardly the hyperæsthesias. On the other hand, it explains conditions which occur outside the range of hysteria, such as the automatisms of epilepsy. Janet may be said, indeed, to have discovered a concept of considerable value throughout the whole range of psychopathology rather than one which will explain all the phenomena of any one part thereof. Secondly, its explanatory value is limited. It enables us to understand that the characters of hysterical anæsthesia or paralysis are due to a splitting of consciousness, but we are immediately faced with the further problem as to *why* this splitting takes place. Dissociation may, in fact, be regarded as an "anatomical" as opposed to a "functional" conception. This is well seen in Prince's "Dissociation of a Personality." In it we have an illuminating analysis whereby the speech and behaviour of a patient is shown to be a manifestation of the activities of a number of distinct personalities, but the question as to the conditions responsible for this splitting—in other words, why the dissociation has occurred—is left without satisfactory answer. Dissociation therefore takes us a certain distance in the understanding of our patients, but leaves us with the further problem of explaining the dissociation itself.

Janet has himself appreciated this limitation, and sought to overcome it by his doctrine of "psychological tension." This is a property which varies in a manner analogous to the pressure of the atmosphere, the variations being produced by constitutional, emotional, and other causes. When it is high, mental processes are integrated with comparative ease and efficient adaptation to reality is attained. When it is low, the required integration is impossible and dissociation of some kind occurs, either the molar dissociation of hysteria or the molecular dissociation of psychasthenia. This is not a very satisfying explanation, however, and seems to come perilously near explaining the incidence of dissociation by a hypothetical capacity of dissociability. It is true that Janet has gone further in that he has emphasised the part played by emotions and the automatic development of affectively toned "idées fixes," and may be said, therefore, to be the forerunner of the dynamic interpretation of the psychoneuroses, but this dynamic aspect is not clearly followed up.

---

[8] It must, of course, be noted that Janet's conception of the subconscious is to be sharply distinguished from the conception of the "unconscious," and that the foregoing argument is not applicable to the latter The "unconscious" will be discussed subsequently. A more detailed treatment of both these conceptions, and of their relationship, will be found in the author's The Conception of the Subconscious, Jour. of Abnorm. Psychol., 1900, reprinted in Morton Prince's Subconscious Phenomena, 1915

[9] Morton Prince: The Dissociation of a Personality, 1906.

The stage in the history of psychopathology marked by the conception of dissociation is comparable to that existing in the history of astronomy at the time of Kepler. Kepler had shown that the planets move in ellipses round the sun, but he could not explain why they did so. This latter achievement was the work of Newton with his formulation of the law of gravity. Newton's step was based on the conception that the phenomena observed were the result of certain hypothetical forces, interacting in accordance with certain precisely definable laws. It thus added a dynamic conception as a means of understanding the observed sequence of phenomena. The corresponding step in the construction of a psychological conception capable of taking us beyond the level reached by dissociation clearly required a similar advance to a dynamic point of view, and it is the attempt to make this advance which actually characterises the later history of psychopathology.

### Dynamic Conceptions in Psychopathology.

The dynamic conception in psychopathology has derived its chief impetus from the work of Freud, but it must not be forgotten that a parallel dynamic aspect made its appearance in academic psychology with the development of the conception of instinct. The view that instinct, or rather various instincts, can be regarded as driving forces whose action and interaction produce the mental phenomena and behaviour of man has received its best-known expression in the work of McDougall. He defines instinct as "an inherited or innate psycho-physical disposition which determines its possessor to perceive, and to pay attention to, objects of a certain class, to experience an emotional excitement of a particular quality upon perceiving such an object, and to act in regard to it in a particular manner, or, at least, to experience an impulse to such action."[10] For example, the instinct of flight determines us to perceive dangerous objects or situations, to experience the emotion of fear, and to act in a manner which will remove us from the source of danger. This definition is open to criticism, and especially is it doubtful whether the position assigned therein to emotion is correct. It would seem that emotion is manifested when the action of an instinct is inhibited—e.g., fear, when it is not possible to remove ourselves from the source of danger—rather than in the normal course of an unobstructed instinct. We are not concerned here with details of this character, however, but only with the general conception of instinct as a driving force capable of explaining the activity of man. It is clear that psychology has thus obtained a dynamic conception enabling it to emerge from the arid paths of academic introspection and mere description to which it was so long condemned. By the aid of this dynamic standpoint a vista is opened up whereby psychology is no longer limited to recording the "how" of the phenomena with which it deals, but can attempt an answer to the question "Why?" It can attempt to conceive the sequence of thought and behaviour in man as a result of the interplay of various instinctive forces acting according to precisely definable laws, and if this attempt is successful psychology will have been lifted from the level of a descriptive science to that long ago attained by such sciences as chemistry and physics.

The question immediately arises, however, whether a psychological conception of this character is permissible in science. The naïve notion that it deals with flimsy abstractions unworthy of being ranked with such solid realities as electrons and ether waves has already been discussed, but there is a more substantial difficulty to be considered. The conception has a teleological aspect, and introduces an element which is not only psychological but which has no correlate or parallel in physics—namely, the element of "purpose." According to McDougall, an instinctive process is not completely explained by a *vis a tergo*. It not only moves towards an end, but the existence of that end is a determining factor throughout, and may continually modify the process during its whole course. In other words, the process not merely happens to serve a purpose, but is actually in part determined by that purpose. Now it is sometimes held that the introduction of purpose as a determining factor is incompatible with the notion of causality, and that, as causality is the foundation-stone of scientific method, no conception involving purpose can have a place in science.[11] A long war has been waged against this mechanistic limitation of science and, although it is obviously impossible here to deal with the subject adequately, something must be said, because to admit this limitation would necessitate the expulsion of modern psychopathology from the domain of science.

Psychological conceptions are characterised by the fact that they are couched in terms of experience, and, as purpose is clearly an integral part of our experience, there is no objection on this score to the incorporation of purpose in a psychological conception. The further question whether purpose is consonant or incompatible with causality requires for its answer a precise definition of this latter word, and it is apparent that it is used in two senses which are by no means identical.[12] In one sense it indicates an unconditional sequence, the fact that (*a*) is inevitably followed by (*b*). In this sense there seems to be no reason why purpose should be excluded from causality; it takes its place as one of the factors determining a particular sequence of phenomena. If we can ascertain the existence of this and the other conditioning factors, and are acquainted with their laws of action, we can predict the course of future phenomena and thus satisfy the essential criterion of the method of science. There is a second sense, however, in which the word causality is used. Here it indicates not merely inevitable succession, but a relation of identity between cause and effect. The effect is regarded as the cause in a new form. For example, when we say that heat is the cause of motion we mean that motion is the equivalent of heat in a new form. Heat is conceived as being the vibration of particles, and hence motion can be regarded as a continuation of the same phenomena. In this sense causality is an equation, and one which is essentially reversible, so that the sequence of cause and effect can be equally well replaced by the sequence of effect and cause. This is the sense in which causality is understood in the mechanistic sciences, and it would seem that it cannot be applied to purposive psychology, for a sequence in which purpose is playing a part clearly is not reversible and cannot be regarded as an equation. The introduction of purpose, therefore, removes psychology from the mechanistic sciences, but this does not justify its removal from the whole field of science. The method of science requires the assumption of causality in the first sense, but not necessarily in the second sense, and in the first sense causality is as integral a part of purposive psychology as it is of any other branch of science. If it were insisted that causality in the second sense is an essential constituent of science, then not only psychology, but physiology and biology also, would have to be excluded, because in the conceptions of all branches of knowledge dealing with life processes irreversibility of the sequences has necessarily to be admitted. The inapplicability of the narrower con-

all : An Introduction to Social Psychology, sixteenth , p. 20.

[11] This is the standpoint taken by Jung, cf. Jung, Analytical Psychology, second edition, 1917, pp. x. and xv. A vindication of "purpose" as an integral factor in psychology will be found in McDougall, An Outline of Psychology, 1923.

[12] Höffding: The Problems of Philosophy, 1905, p. 66.

cept of causality is not, therefore, a peculiarity of psychology, but a peculiarity of all the biological sciences, and the circumstances we have considered merely indicate that psychology is extra-mechanistic, but not extra-scientific.

### THE THEORIES OF FREUD.

This digression has been necessary in order to justify the incorporation into science of conceptions involving the element of purpose, and we may now return to the later history of psychopathology in which conceptions of this character play a prominent part. This later history is inseparably bound up with the work of Freud, to whom the most noteworthy advances in psychopathology are unquestionably due, whatever view we may ultimately reach concerning the validity of many of his doctrines.

Freud's conceptions have undergone an extensive development during the course of his career, and it is impossible here either to trace out this development in detail or to give any adequate account of his theories as they stand to-day. An acquaintance with their general characters must be assumed, and we shall select for consideration only certain broad features which are relevant to our present problem.[13]

In 1880 Josef Breuer, of Vienna, investigated a case of hysteria in which he observed the traumatic effect of certain memories of which the patient was unconscious, and the therapeutic result obtained by bringing these memories once more into consciousness. This investigation, although it was not published until many years later, was the starting point of Freud's work. In 1893 he brought out, in association with Breuer, a preliminary paper, and in 1895 the "Studien über Hysterie," which may be said to express the first stage of Freud's development. The keynote of this stage, the view that "the hysteric suffers mainly from reminiscences," is not essentially different from Janet's notion of "idées fixes," which certainly preceded in time Breuer and Freud's publication, although it is claimed that the latter had a quite independent origin. There is apparent in the work of Breuer and Freud, however, a much more definite dynamic formulation than Janet had attained, and new conceptions of fundamental importance, such as "repression" and "resistance," were laid down. To this period belongs the use of hypnosis as a method of recovering buried memories, the conception of "psychic trauma," and treatment by "catharsis"—that is to say, the bringing to consciousness of the traumatic memory and its "abreaction" by allowing it to obtain the normal emotional expression which had formerly been denied to it We need not concern ourselves here with these conceptions except to note that hypnosis was abandoned by Freud many years ago, as was also the notion of "psychic trauma," and that treatment by catharsis only bears a remote resemblance to the modern method of psycho analysis.

After the dissolution of the partnership between Breuer and Freud the latter proceeded independently and produced a succession of works in which the earlier conceptions were considerably modified, extended, and made more systematic and precise. Although the development has been continuous, it will be convenient to postpone for the moment the consideration of the later additions, and to devote our attention to the theories as they stood before the war. The essential structure, with which we are alone concerned, remains the same to-day, but it is easier to see and to examine without the accretions and amplifications of the last decade.

The essential structure may be very briefly and inadequately sketched as follows. The phenomena of conscious life and behaviour are conceived as the result of the interaction of a number of psychological "forces" which interact according to precisely definable "laws." These forces, which are in part conscious and in part unconscious, may work harmoniously together, or they may conflict with one another. In the latter case an attempt at adjustment occurs, and this attempt may proceed in various possible ways. Certain of these ways involve the repression of one of the opposing forces—that is to say, one of the forces is put out of gear, as it were—and is no longer allowed to manifest itself normally in consciousness or in action It becomes unconscious, but does not thereby cease to exist or to be capable of functioning. It can no longer influence thought and behaviour in a normally direct manner, but it produces various indirect effects. For example, the sex instincts in an elderly unmarried woman, repressed because of their incompatibility with her moral code, and with the circumstances of her life, may express themselves in consciousness as an abnormal interest in births, marriages, and scandals. These indirect effects manifest themselves by means of certain mechanisms which Freud precisely defines, such as compromise, condensation, representation by the opposite, and so forth. Mechanisms of this character are responsible for many phenomena in everyday life, slips of the pen and of speech for instance, for the content of dreams, and for the various symptoms manifested in the psychoneuroses.

It must be understood that the foregoing is only an attempt to describe in general terms the supporting columns on which Freud's theories appear to rest, and does not correspond to the actual way in which these theories were developed. Freud's attack was entirely empirical, and he subjected the psychoneuroses to a prolonged clinical study, only slowly and tentatively building up theoretical conceptions to account for the phenomena which he had observed. It will be noted that, in form at least, this course is entirely irreproachable from the standpoint of the canons of science. After his abandonment of hypnotism as a means of investigation he evolved the method of psycho analysis, and it is by the use of this method that practically all the facts of observation upon which the Freudian theories rest have been collected. We shall have subsequently to describe it, and to evaluate its claim to rank as a trustworthy instrument of research. At present, however, we are concerned with the results of its employment rather than with the instrument itself.

In the course of his psycho-analytic investigations of the phenomena of the psychoneuroses Freud noted that the conflicts underlying the symptoms were invariably conflicts between forces belonging to two radically distinct groups. The first group comprised forces apparently emanating from the sex instincts, the second group forces connected with the personality. To the first Freud gave the name of "libido," to the second that of "the ego," and he conceived that a psychoneurosis developed owing to a certain failure of adjustment between these two or, as he has himself expressed it, "when the ego loses its capacity to deal in some way or other with the libido"[14] In view of the important part played by the libido Freud subjected this to a careful examination in order to determine its precise mode of development, and as a result of this examination he reached the remarkable conclusions constituting the well-known "sex theories." According to these theories sex, as we know it in the adult, is not a function which suddenly emerges at puberty in a manner comparable to the birth of Minerva, but is the final stage in a long process of development starting from the dawn of life. Although its early manifestations are very different from the adult function, the term sexual can justly be applied to the former, because the latter is clearly developed therefrom. Moreover, many tendencies not generally regarded as sexual—for example, parental and filial love, and indeed all the processes to which the word "love" can be applied—must similarly be brought within the sphere of the libido, because they also can be shown to originate from the common fount. The earlier stages in the development of the libido are distinguished by differences both in the objects towards which the libido is directed and in the parts of the body with which the libido is associated, and these differences characterise definite stages through which the libido passes in its progress to adult normality. Thus in the earliest stages the libido is directed on to the individual himself, later on to one or both parents, and only in its final development is it directed on to other persons of the opposite sex. Similarly in earlier stages the libido is associated with other parts of the body than the genitalia—for example, the mouth and anus—and only later does the genital zone assume the primacy which characterises adult sex.

---

[13] Freud's chief works are: Studien über Hysterie (with Breuer), 1895, Die Traumdeutung, 1900, Zur Psychopathologie des Alltagslebens, 1901, Drei Abhandlungen zur Sexualtheorie, 1905; numerous shorter papers collected into the Sammlungen kleiner Schriften zur Neurosenlehre, Vorlesungen zur Einführung in die Psychoanalyse, 1917, Jenseits des Lustprinzips 1920 Massenpsychologie und Ich Analyse, 1921; Das Ich und das Es, 1923 Practically all have now been translated into English.

[14] Freud Introductory Lectures on Psycho-analysis, English translation, 1922, p 333

Freud observed that the psychoneuroses were associated with a failure in this process of development, the normal evolution being partially arrested at an early stage. A very important stage in this respect was that at which the libido was directed on to one of the parents, generally the parent of the opposite sex. A failure of adequate development here meant that the libido was fixated at this stage and could not undergo its normal evolution. This fixation was invariably found in certain types of psychoneurosis, and the conflict, which resulted when the claims of later life demanded a normal distribution of the libido, was responsible for the outbreak of the symptoms. In other conditions fixation at other levels were found to be present, and in a word the whole structure and development of the psychoneuroses could be worked out in each individual case by the application of these conceptions.

This description, condensed and generalised to an extent which is hardly consistent with accuracy, will have to serve for our immediate purpose—namely, the estimation of the Freudian theories, both in their form and content, by the canons of scientific method. To begin with, it is clear that with conceptions of this character a goal has been attempted far beyond that achieved by the dissociation conception of Janet. The essential mark of the advance lies in the move forward to a dynamic point of view, and the endeavour to account for the observed phenomena by the action of precise forces working according to precisely definable laws. Similarly the goal attempted is far beyond that reached by the suggestionist and persuasionist schools, because, although suggestion is a dynamic concept, it is immeasurably inferior in precision and manageability to the concepts which Freud has constructed. It is unnecessary to point out, therefore, that Freud's attempt is a very notable one, and if it can be established, either in whole or in part, it must rank amongst the great achievements of the world. The importance of ascertaining how far his methods are consonant with the method of science, and how far the observed facts justify his conclusions, cannot be overestimated, and the magnitude of the issue requires that this should be done with the utmost care and consideration. We may endeavour to approach the problem by a preliminary examination of certain of Freud's fundamental conceptions, and may take in order the conception of the unconscious, the mechanisms, and the sex theories.

### FREUD'S CONCEPTION OF THE UNCONSCIOUS.

The conception of the unconscious is an integral part of Freud's theories. He holds that the processes we term conscious are only a superficial layer, as it were, of the total sum of mental processes. There are two other layers—the preconscious, comprising those processes which, although not conscious at the moment, may at any time become so; and the unconscious, comprising processes which are not only not conscious at the moment, but are prevented from becoming conscious by a barrier only to be circumvented under special circumstances. The unconscious processes are nevertheless able to influence consciousness in various indirect ways. Freud formulates very pre[illegible] the nature, characters, and mode of action [illegible] contained in the unconscious.

The conception of the unconscious has been subjected to much adverse criticism. It is said that it involves a contradiction in terms, as consciousness is the essential character of mental processes, and an unconscious mental process therefore an absurdity; that the processes in question are not psychological at all, but physiological, and that they should be conceived not in terms of consciousness, but in terms of brain. These criticisms arise from a confusion of thought. The unconscious is not a phenomenal reality, but a concept fashioned in order to explain the phenomenal reality. The phenomenal reality, consciousness, obviously forms a disconnected series and, if the psychologist is compelled to take only this into account, he cannot rise beyond the level of a mere description of psychic phenomena. To obtain understanding and continuity it is necessary to go beyond the phenomena and to construct an explanatory concept. The physiologist has, of course, a perfect right to construct for this purpose a concept in terms of brain, but he cannot deny to the psychologist an equal right to construct a concept in psychological terms. The question is not whether one is correct and the other incorrect, but which one works the best in the present state of our knowledge. So far as the phenomena which Freud seeks to explain are concerned, the physiologist cannot yet give an explanation which consists of more than words, and the fact that these words indicate hypothetical material processes rather than hypothetical psychical processes is an inadequate consolation for his entire inability to make any use of the conceptions he fashions. The psychologist is therefore perfectly justified in attempting to find an explanation by the construction of a psychological conception, at any rate until the physiologist can provide one which is practically more useful, and such a conception must involve the assumption of an unconscious in one form or another. If consciousness is defined as the essential attribute of mental processes, then, of course, the "unconscious" becomes a contradiction in terms, but as the question is already begged by accepting the definition this is not of much moment. We saw, when discussing Janet's conception of the subconscious, that there is convincing proof that mental processes exist which are not personally conscious, and such processes are unconscious from the standpoint of the personal consciousness. It may be added that, even if the notion of the unconscious were contradicted by our experience of phenomenal reality, this would not necessarily preclude it from ranking as a scientific concept, because a concept is a construct and not a phenomenal reality. An unconscious mental process, for example, would not be more absurd than a weightless and frictionless ether. Criticisms directed against the unconscious as a possible conception do not carry much weight, therefore, and we have seen that a conception of this kind is necessary if the psychologist is to be allowed to explain the phenomena of consciousness in psychological terms.[15] The question whether Freud's particular conception of the unconscious is valid is, of course, another matter. On the score of method there is no objection whatever to its form and structure, but to satisfy the canons of science it must be shown that it is based on accurately observed facts, that it explains those facts, and that the deductions which follow from it when tested by experience and experiment are always found to be verified. These are the only criteria which have any relevance if the value of Freud's concept is to be satisfactorily estimated.

The mechanisms—that is to say, the modes of action whereby the various intrapsychic forces produce the phenomena they are invoked to explain—need not be considered in detail. Here belong the conceptions of conflict, repression, and the effects upon consciousness and behaviour which a repressed system is capable of producing. This portion of Freud's work has obtained wide acceptance and recognition, extending far beyond the limited circle of Freud's orthodox followers, a circumstance due in some part to the fact that the principles in question were found to be remarkably applicable and illuminating in the study of that great mass of psychoneuroses produced by the war. Here, again, the conceptions are certainly constructed legitimately so far as their form is concerned, and their validity must be determined, as in the case of the unconscious, by an appeal to the facts and to experience.

---

[15] Freud's conception of the unconscious differs fundamentally from Janet's "subconscious," and the considerations which justify the one are not applicable to the other. *Cf.* footnote (8).

In contrast with the comparatively favourable reception accorded to the mechanisms, the sex theories have been the subject of most vigorous attack and rejection. Certain criticisms have been based, sometimes explicitly, but more often implicitly, on ethical or æsthetic grounds. Objections of this kind have, of course, no place or relevancy in positive science, and only require to be mentioned in order that they may be at once dismissed. Other criticisms have more weight. It is held that to reduce all the phenomena of the psychoneuroses to the action of the sex instincts is an unduly narrow view, and that other instinctive forces without admixture of sex elements are equally capable of causing these disorders. It would seem, for example, that the psychoneuroses of the war were certainly due to intrapsychic conflicts, but to conflicts between forces in which sex played no part. We shall see subsequently that the Freudian school has met this latter objection with regard to the war psychoneuroses by a further extension of the already wide denotation ascribed to sex. For the moment, however, it is merely necessary to note that disputes of this kind can only be settled by an appeal to the facts of observation, and not by a priori considerations. A generalisation is unduly wide only if it can be shown that the facts do not fit into it, and it is no more inherently impossible that the sex instinct should account for all the phenomena of the psychoneuroses than that so simple a principle as gravity should account for all the movements of the planets. Once more, therefore, we are led to the conclusion that we cannot quarrel with the form in which Freud's sex theories are cast, and that they are legitimate attempts to explain the facts. As in the cases of the unconscious and of the mechanisms, the crux of the matter is whether these conceptions do fit the facts, and fit them in a manner satisfactory to the canons of science. It is unfortunately necessary to labour this simple and obvious point, because many critics of Freud appear to forget that all theories can only be appraised by an examination of the facts, and that, just as a theory can only be legitimately constructed on the careful observation and recording of phenomena, so it can only be destroyed by recapitulating the observations or, as it were, making control experiments. This essential work is often altogether neglected, and its place taken by ex cathedra statements, whose foundations in prejudice are sometimes only too obvious. An examination at the level of the facts of observation, therefore, must clearly be the chief task in any reasonable attempt to judge the value of Freud's conceptions.

---

THE LATE DR. G. E. GABITES, O.B.E.—News has been received of the death on Jan. 5th of Dr. George Edward Gabites, a well-known member of the medical profession in South Canterbury, New Zealand. He was born in Christchurch in 1867, and after being educated locally, went to Edinburgh, where he graduated in science at the University in 1891, proceeding to the M.B., C.M. three years later. He was appointed resident physician at the Royal Infirmary and later became resident surgeon at the Royal Maternity and Simpson Memorial Hospital, and medical superintendent at the Edinburgh Provident Dispensary. In 1898 he obtained the Fellowship of the Royal College of Surgeons of Edinburgh and in 1899 was appointed surgeon superintendent of the Timaru Hospital, New Zealand. Subsequently he served in the South African War with the New Zealand contingent and for his services was awarded the Queen's Medal with four clasps. During the late war he was Captain Commandant of the N.Z. Medical Corps in the training camp at Arapuni, and was A.D.M.S of the Otago military district. Dr. Gabites leaves a widow and two sons.

# THE TREATMENT OF ILEUS BY CHOLINE.

By C. G. L. WOLF,* M.D. McGILL,
HON. BIOCHEMIST, ADDENBROOKE'S HOSPITAL, CAMBRIDGE;
AND
J. R. C. CANNEY, M.D. CAMB.,
HON. ASSISTANT SURGEON TO THE HOSPITAL.

WHILE engaged in an investigation of the rhythmic movements of the small intestine in 1912 Weiland made the chance observation that when a piece of isolated intestine was allowed to contract in Ringer's solution for some time the fluid acquired the property of exciting contraction in other pieces of intestine placed in it. Le Heux, another worker in Magnus's laboratory in Utrecht, isolated the substance causing this effect and identified it as choline. This base has come into prominence at various times in physiological literature and is related chemically to muscarine, the principle found in poisonous mushrooms. Le Heux was able to transform the small amount of choline obtained into acetyl choline, and obtained the powerful physiological effects observed by Reid Hunt and by Dale.

It is known that when the alimentary canal is nearly completely cut off from its central nervous supply by severing both vagi and both splanchnic nerves digestion proceeds almost undisturbed. The normal rhythmic movements of the gastro-intestinal canal continue without hindrance. The plexus of nerves known as Auerbach's plexus, existing between the longitudinal and circular layers of the musculature of the intestine, evidently receives its stimulus elsewhere than centrally.

We know that the rhythmic movements of respiration are initiated by changes in carbon dioxide or hydrogen-ion concentration in the blood. It was the analogy with the action of carbon dioxide which led Magnus to conclude that choline acts as the hormone of intestinal movement. That choline is specific in its action on the intestine is shown by the fact that it does not affect the rhythmicity of the heart or of the uterus.

The origin of choline is still unknown. Neither the food nor the suprarenals appear to be the source of the base. The intestine endeavours to retain its store of choline, and it is found in the intestinal wall even in conditions such as prolonged chloroform narcosis and peritonitis. It is known that the salts of acetic and pyruvic acids stimulate peristalsis strongly and the reason for this action is now clear. It is the choline esters of these two organic acids which have a powerful effect on intestinal movement; indeed, the acetic ester of choline is 1000 times as powerful as the base itself in exciting peristalsis. It would seem, therefore, that the acid radicle couples up with choline in the intestinal wall and produces an effect which has hitherto been ascribed to the acetate or to the pyruvate alone.

In a series of articles by workers in Magnus's laboratory it was shown that paralysis of the bowel produced in cats by long-continued chloroform narcosis was speedily relieved by the intravenous injection of 5–15 mg. of choline per kilo body-weight of choline hydrochloride. Strong gastro-intestinal movement, as seen by X ray photographs, took place almost immediately, followed by evacuations in the following 20 hours.

Arai brought about peritonitis in cats by the intraperitoneal injection of iodine solution. Depending on the dose, any degree of ileus could be produced. The paralysis was overcome by an injection of choline. The production of a typical operative ileus in animals simulating that seen in man was successfully imitated by exposing the intestines of an animal to the air through an abdominal incision combined with manipulation. In such cases no evacuation of fæces

---

* Assisted by a grant from the Medical Research Council.

took place in 30 hours unless choline was administered. When this was done a normal stool followed in a short time.

Finally, Arai produced a severe infective peritonitis in cats by the injection of a mixture of *B. coli* and staphylococci. In those animals which survived there occurred intestinal paralysis. The injection of choline resolved the ileus. An analysis of the intestinal wall showed that a normal content of choline was present. The paralysis was due to a lessened sensitivity of Auerbach's plexus. Only when the choline content of the blood was raised above the normal did this nerve system respond with increase of tonus and peristaltic movement.

Following on the work of Arai, Magnus investigated the toxicity of choline with a view to using it therapeutically. It was found that the safe dose in cats by intravenous administration was 20 mg. per kilo. Much larger concentrations were borne when the drug was injected intravenously at a slow rate. When injected in the amount of 0·8 mg. per kilo per minute large amounts could be borne without the least distress. The work of Le Heux shows that choline hydrochloride solutions decompose and become toxic unless they are specially prepared and kept in ampoules of resistant glass. Messrs. Merck put up the sterile solution in ampoules in a way which fulfils the requirements of Magnus and Le Heux. When properly prepared the solutions will remain undecomposed for at least four years.

The administration of choline in cases of ileus was taken up by Klee and Grossmann in Romberg's clinic in Munich and a report presented at the Congress for Internal Medicine in Vienna in 1923. It was used in peritonitis, in chronic atony of the stomach and intestines, and in atonic constipation. In all these cases its use was successful. Its value in nervous dyspepsia could be accounted for by the fact that treatment of decerebrate cats with choline did not permit subsequent inhibition of the stomach movements by stimulating the sympathetic.

Through the kindness of Prof. Magnus, one of us was given a supply of choline hydrochloride and with it the following cases have been treated. The number is small, but, as far as we are aware, no reports of its use have appeared in England. It was thought it would be of service to give the results of its administration.

### *Clinical Records.*

CASE 1.—Mrs. S., aged 47. On March 21st, 1923, panhysterectomy was performed for a very large fibroid uterus filling the whole pelvis and extending 1¼ in. above the umbilicus. 24th: Much distension and pain for past 24 hours. Frequent vomiting with slight rise of temperature. Several high enemata with turpentine failed to relieve, and no flatus was passed. That evening the incision was reopened, and a considerable amount of slightly blood-stained peritoneal fluid was evacuated. The large intestine was hardly distended, but the coils of small intestine which presented were very much so. It was found that after removal of the pelvic tumour its place had been taken by quite half the small intestine. This also was distended and to some extent imprisoned in the pelvis. The mesentery had become much stretched, especially over the sacral prominence, and there were signs of early thrombosis in the mesentery which was œdematous. The coils were freed and the incision closed. 25th: No improvement. Choline administered with no effect, the patient dying the same night.

*Summary.*—A case of intestinal paralysis due to distension and partial fixation of coils of small intestine which, after removal of a large pelvic tumour, had taken its place. Choline was administered when it was proved by exploration that intestinal obstruction was absent. The administration was too long postponed and no chance therefore was given to test its value.

CASE 2.—Mrs. G., aged 75. June 21st, 1923: Panhysterectomy was performed for adenocarcinoma and the patient stood the operation exceedingly well. 23rd: The patient did well to date, but was getting uncomfortable with distension. Pituitrin followed by enemata resulted in the passage of small quantities of flatus only. 24th: Further enemata after [illegible] of eserine failed to produce any result, and the [illegible] getting exceedingly distressed. At 6 P.M. choline was administered. Immediately afterwards she complained that she was soiling the bed. This was so, but only to a slight extent. During the night colicky pain was very much complained of, and a gravitation enema early next morning produced a fair result. Eserine and enemata were persevered with and the bowels commenced to act well. She made an uninterrupted recovery and is now, two and a half years later, in perfect health.

*Summary.*—A case of ileus following prolonged and severe operation in an elderly stout woman. Choline appeared definitely to restore muscular tone and contraction in the intestinal wall.

CASE 3.—Mrs. R., aged 38. Sept. 23rd, 1924. This patient had had a precipitate labour on the previous day and was admitted to hospital as a case of acute intestinal obstruction. She complained of much abdominal distension, and for 24 hours no flatus had passed in spite of enemata. She had vomited twice. She stated that she felt well except for abdominal uneasiness. The abdomen was greatly distended, but there was no rigidity. Numerous coils of much distended gut could be seen through a thin abdominal wall. That afternoon the patient vomited again. In the evening, as the pulse had risen and an enema had failed to produce even flatus, it was decided to explore, though her general condition as a whole remained excellent. It was thought advisable not to await the onset of a more critical condition. A mesial hypogastric incision was made and the whole intestine was found uniformly distended. No cause of obstruction could be detected. A large rectal tube was passed a good 18 inches, aided by a hand over the pelvic colon within the abdomen. Much fluid fæces and flatus were passed by this means before the patient left the table. 24th: The distension was as great as before, but the general condition remained good. Enemata through the rectal tube, still in situ, failed to produce any result. 25th: The same condition as on the previous day with no relief of symptoms and signs. 4.30 P.M., choline administered. Within 20 minutes of the administration ending a copious motion was passed, followed by another later in the evening. 28th (three days after choline): The bowels had been acting normally for two days with the aid of mild laxatives.

*Summary.*—A case of pure ileus following the sudden emptying of the abdomen of a large tumour (full term ovum). At first thought to be an acute intestinal obstruction. This disproved by abdominal section. Choline immediately re-established intestinal function after all other remedies had failed over the space of three days.

CASE 4.—Mrs. M., aged 34. Dec. 2nd, 1924: The patient was admitted to hospital as an emergency at the end of her eighth month of pregnancy, as there had been irregular losses throughout pregnancy and she was bleeding freely at the time. The cervix admitted one finger and a central placenta prævia could be felt. There were no pains. It was thought that the best treatment was immediate delivery by Cæsarean section, and she stood the operation exceedingly well. 6th: Patient has had considerable colicky pain requiring morphia. 7th: There was much vomiting and great distension with a rapid poor-volume pulse. A turpentine gravitation enema following 0·5 c.cm. of pituitrin, though producing a slight result, did not relieve either the distension or the distress. 9 P.M.: Choline given. Some flatus passed during the night. 8th: Pituitrin 0·5 c.cm. and eserine gr. 1/100, followed by a turpentine enema, produced a good result. 9th: The same good result followed similar treatment. By the next day the normal intestinal function had become established.

*Summary.*—An otherwise healthy woman suffering from acute ileus as the result of suddenly emptying the abdomen of a large tumour (full term ovum) by abdominal section. Choline re-established the normal intestinal function within 36 hours.

### *Conclusion.*

The administration of choline is a simple matter. Sterile choline hydrochloride is put up in glass ampoules containing 600 mg. in 6 c.cm. This solution is diluted with 180 c.cm. of sterile normal saline and the resulting solution injected intravenously. An important point in administration is that it should take at least 17 minutes to inject the whole quantity. On every occasion except one an ordinary saline infusion apparatus with a narrow intravenous needle was used.

# THE AMOUNT OF ANTITOXIN TO STREPTOCOCCUS SCARLATINÆ PRESENT IN THE BLOOD OF CONVALESCENT SCARLET FEVER CASES.

A REPORT TO THE MEDICAL RESEARCH COUNCIL.

BY HERBERT HENRY, M.D. LOND.,
AND
F. C. LEWIS, M.R.C.S. ENG.
*(From the City of Birmingham Bacteriological Laboratories.)*

IN a previous report[1] it has been shown that a ready means of obtaining the toxin of *Streptococcus scarlatinæ* consists in the preparation of "floating" surface cultures of the organism on serum agar Roux bottles, and in the separation of the condensation water from these after 24 hours' incubation. At this period in our observations there was little evidence from American sources in regard to the stability of the toxin, apart from its apparently remarkable resistance to heat, and we deemed it necessary to make attempts to obtain the toxin in dried form. As a result of these experiments it was found that fractional precipitation with alcohol provided in dried form a toxin of considerable concentration, and subsequent experience with products so prepared and kept in desiccators over sulphuric acid has proved that these sustain no detectable loss in potency over a period of ten months.

TABLE A.—*Scarlet Fever Convalescent Children.*

| No | Sex. | Age. | Day of disease. | Blood-group | Amounts of serum titrated against five skin test doses. | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | | | | 0·1 | 0·04 | 0·02 | 0·01 | 0·004 |
| 2 | F. | 12 | 33 | 1 | − | − | − | + | + |

| 40 | M. | 8 | 24 | 3 | − | − | + | .. | .. |
| 41 | M. | 8 | 23 | 2 | − | + | + | .. | .. |
| 43 | F. | 11 | 40 | 1 | − | − | + | .. | .. |
| 44 | M. | 11 | 49 | 2 | − | + | + | .. | .. |
| 45 | M. | 6 | 32 | 3 | − | + | + | .. | .. |
| 48 | M. | 9 | 24 | 3 | − | + | + | .. | .. |
| 49 | M. | 7 | 33 | 1 | + | + | + | .. | .. |
| 51 | F. | 11 | 44 | 2 | − | + | + | .. | .. |
| 53 | M. | 5 | 36 | 2 | + | + | + | .. | .. |
| 55 | M. | 4 | 42 | 2 | + | + | + | .. | .. |

A particular specimen of toxin prepared in the way just referred to was then used for intradermal test on a large number of individuals[2] each of whom was submitted not to one dose of toxin but to a small series of graduated dilutions. The advantage of this multiple dose titration lies in that it gives information not only that an individual may be resistant to one particular dose of toxin, as does the ordinary Dick test, but that it also affords a rough measure of the degree of resistance of that individual and assigns to him a position on an immunity scale. The method, therefore, has enabled us to classify individuals as coming into one or another of a series of "immunity groups." Those who react positively to the smallest amount of toxin in the scale of titration—viz., 1 unit—are the most susceptible and are said to belong to Group VI., whereas those who react negatively to 16 units are the most resistant of all and are aggregated in Group I.

Such a classification, resting as it does on the hypothesis that the degree of reaction to the toxin affords an index of the degree of immunity, is justified only if the assumption is proved to be correct. That this is so we were able to show in our previous report, for we found that the blood of four susceptible individuals contained little or no antitoxin, whereas the blood of four resistant individuals contained antitoxin in considerable amounts.

The present report concerns itself with an amplification of these last-mentioned experiments and deals with an attempt to determine the antitoxin content of a series of 40 specimens of blood, collected in the Birmingham City fever hospitals, half being taken from children who were convalescent from scarlet fever, the other half from children in whom there was, as far as could be ascertained, no previous history of this disease. Toxin reactions had not been done on these children, so that there is no evidence from this source to correlate with our observations. There was no selection of cases except in so far as to exclude (1) adults, and (2) children in which the diagnosis was doubtful on clinical grounds.

TABLE B.—*Non-Scarlet Fever Children.*

## *Technique.*

To the serum separated from clotted blood by centrifuging there was added trikresol in the proportion of 0·35 per cent. Each sample, placed in a rubber-corked tube, was then stored in the cold room for three to ten days before use. Toxin-antitoxin mixtures were made by adding 0·5 c.cm. of toxin containing 25 skin test doses (or 50 units) *to 0·5 c.cm. of* serum in a series of dilutions. The specimen of toxin employed was the same as that used in previously recorded experiments.[2] The amounts of serum in each total mixture of 1·0 c.cm. were as follows: 0·5, 0·2, 0·1, 0·05, and 0·02 c.cm. The mixtures were made up and kept at 37° C. for one hour immediately before use. The actual dose of each mixture used for intradermal inoculation amounted to 0·2 c.cm., so that it consisted of five skin test doses of toxin mixed with one-fifth of the volume of serum just mentioned.

As there is not yet a satisfactory animal test for the estimation of the toxin of *Streptococcus scarlatinæ*,

recourse must be had to human skin. The only human individuals possessing skin suitable for the test are those who are sensitive to small amounts of toxin—i.e., those who are classified together in Groups V. and VI. These comprise the bulk of children of junior school age who have not had scarlet fever and a small proportion of ordinary adult males and females. There are many reasons why this large series of tests should not be carried out on children, and we were fortunate in having at our disposal an adult male who was eager that we should use him as much as we should consider necessary. This lucky circumstance we gladly seized upon, as it gave us the opportunity of estimating in a short space of time the antitoxic titre of the 40 sera, and, moreover, it afforded us strictly comparable findings as between one serum and any other throughout the whole series, a result which would have been unattainable had use been made of a number of suitable volunteers.

The whole period taken up by the inoculations occupied 14 days, a batch of five to ten sera being given at one time and followed by one or two days of rest. Readings were taken 24 hours after inoculation, and are recorded as follows :—

+ = a reaction equal to or larger in area than that covered by one skin test dose.

– = no reaction, or a reaction smaller than that caused by one skin test dose.

Except for slight dissociation in the case of the first five sera to be tested, no difficulty was experienced in reading reactions until we reached the last quarter of the series. Then it became apparent that the individual whom we were inoculating was reacting to some constituent of the toxin other than the toxin itself. A series of tests showed him to be sensitive to rabbit serum and also to some ingredient of the condensation water taken from salt agar tubes which contained no peptone or meat extract. The combination of these two factors resulted in the production of what may be termed a pseudo-reaction which tended to mask the negative reactions and also to emphasise the positive ones. It would appear, therefore, that an increased susceptibility to a pseudo-reaction must be borne in mind in interpreting the results of a large series of inoculations in any one individual. In this particular instance the reactions obtained at the end of the series were still readable, though with difficulty, and we do not feel that the individual could be profitably used for further injections of a similar character until he has lost his sensitiveness.

### *Results.*

The findings in respect of the reactions in individual scarlet and non-scarlet children are set out in Tables A and B respectively. The results show that the differentiation between these two groups in regard to their antitoxin content is as follows :—

1. If the unit of antitoxin be taken as that amount which gives complete neutralisation of one skin test dose, then out of 20 scarlet fever children 17 were found to yield a serum which contained 50 units or more of antitoxin, whereas of the non-scarlet children only eight reached this titre. 2. Of the 20 scarlet children nine yielded a serum containing 125 units or more, whereas only three of the non-scarlet children did so. 3. The 250 unit level was reached by five scarlet children and by one non-scarlet child.

The blood groupings of these children were determined for a purpose other than that with which the present report concerns itself. It is of some interest, however, to note that, although the distribution of the groups taken throughout the whole collection of sera approximates the normal, yet there would seem to be a preponderance of Group II. individuals among the scarlet fever convalescent children and of Group I. individuals in the non-scarlet series.

# HERPES ZOSTER OTICUS AND ALLIED CONDITIONS,

## WITH NOTES OF THREE CASES.

By THOMAS GUTHRIE, M.B., B.C. Camb., F.R.C.S. Eng.,
HON. LARYNGOLOGIST TO THE LIVERPOOL ROYAL INFIRMARY; HON. LECTURER IN LARYNGOLOGY, LIVERPOOL UNIVERSITY.

Herpes zoster of the skin of the auricle was described and figured many years ago. In the second edition of Gruber's book on the ear, published in 1890, mention is made of its association with nerve deafness, while Politzer, in the fourth edition of his text-book (1902), refers to facial palsy as yet another feature of some of these cases. But the credit for the first complete description of the interesting syndrome, known to-day as herpes zoster oticus, is due to J. Ramsay Hunt, to whose writings I am indebted for much of what follows. In 1907 and 1908 he gave a detailed account of the disease and its complications based on four cases observed by himself, together with 56 others collected from the literature.

It is well known that herpes zoster affecting an area on the trunk or limbs is due to an inflammation of one or more of the ganglia of the posterior or sensory roots of the spinal nerves. These ganglia contain cells of the unipolar type, and with the sensory or afferent portion of certain of the cranial nerves are associated ganglia containing similar unipolar cells, and clearly representing posterior root ganglia. One of these is the geniculate ganglion of the facial nerve. This ganglion receives its afferent fibres from the sensory portion of the nerve which consists not only of the chorda tympani, but also of fibres from a certain well-defined area of skin. These are incorporated in the auriculo-temporal branch of the third division of the fifth nerve and in the auricular branch of the vagus, and reach the ganglion through its connexions with these nerves.

The area of skin affected by herpetic inflammation of the geniculate ganglion is intercalated between the areas affected in herpes occipito-collaris and in herpes facialis, which are due respectively to disease of the upper cervical and of the Gasserian ganglia. The vesicular eruption is limited to " a cone-shaped area with its apex on the tympanic membrane and its base of the auricle " (Hunt), consisting of the tympanic membrane, external auditory meatus, concha, tragus, antitragus, lobe (outer surface), antihelix, and fossa antihelicis.

As the motor fibres of the facial nerve are closely applied to the ganglion the inflammatory process readily spreads to these, and the result is facial paralysis, which was noted in all the cases of herpes zoster oticus collected by Ramsay Hunt. Often the inflammation extends further and affects both the cochlear and the vestibular portions of the eighth nerve, causing nerve deafness, tinnitus, vertigo, and vomiting. This occurred in 19 of Hunt's cases. Moreover, just as in herpetic inflammation of the spinal ganglia, while one ganglion is chiefly affected, those on either side of it tend to suffer in a less degree, so in certain cases, presenting some or all of the ordinary features of geniculate ganglion disease, there may be also indications of coincident herpetic inflammation of other ganglia, such as the Gasserian or the second, third, and fourth spinal ganglia. It is probable indeed that occasionally the eighth nerve ganglia of Corti and Scarpa are *directly* affected, since these ganglia are developmentally homologous with posterior root ganglia. The resulting symptoms (deafness, vertigo, &c.) will then be clinically indistinguishable from those met with in typical cases of herpes zoster oticus in which the *trunk* of the eighth nerve is affected by inflammation spreading from the geniculate ganglion. In this way are probably to be explained certain cases of herpes occipito-collaris and herpes facialis with eighth nerve symptoms, but without geniculate ganglion involvement.

Herpes zoster oticus is a rare condition. It is met with in about 1 in 20,000 cases of ear disease Pain about the pinna and mastoid region may be severe and may be present for two or three days before the eruption appears It was the first symptom in one of my cases, and in another was preceded by the vertigo It is sometimes present also in the distribution of the upper cervical and the fifth nerves, due to coincident inflammation of the corresponding ganglia, or in the case of the fifth nerve to its connexion with the geniculate ganglion through the great and small superficial petrosal nerves

As the eruption affects the tympanic membrane and skin of the meatus as well as the pinna, there may be, two or three days after it has appeared, much inflammatory swelling of the meatal walls with otorrhœa and sometimes secondary swelling of the mastoid lymphatic gland These appearances, together with the intense pain, deafness, facial palsy, and sometimes pyrexia, are very suggestive of acute otitis media with mastoiditis, for which cases of herpes zoster oticus are occasionally mistaken Points of importance in the diagnosis are (1) the nature and distribution of the eruption; (2) the type of the deafness—namely, inner- and not middle-ear deafness; (3) loss of taste in the corresponding side of the tongue, owing to affection of the chorda tympani nerve; (4) absence of perforation of the tympanic membrane, although its appearance may be much altered by the eruption, and, in any case, an intact drum does not of course exclude disease of the middle ear

The duration of the disease varies considerably Some degree of neuralgic pain usually persists for two or three weeks. The facial paralysis may be evanescent, lasting only a few days, or it may disappear gradually during the course of some weeks The same applies to the deafness and other symptoms of eighth nerve involvement. In rare cases some degree of facial palsy and nerve deafness is permanent

Treatment consists of sedatives for the pain, the usual local applications for the herpetic eruption, and massage and electrical treatment for the paralysis if this persists

### *Clinical Records*

The following are brief notes of three cases which I have observed, the first two being characteristic examples of herpes zoster oticus, and the third a case of herpes facialis with eighth nerve symptoms.

CASE 1—A man, aged 56, whom I saw at the request of Dr John Hay, was in bed suffering from vertigo and vomiting, which began ten days before I saw him. For eight days there had been pain in and about the left ear and a vesicular eruption had developed on the pinna. Three or four days after the onset of the pain left facial palsy had appeared. His temperature had varied between normal and 103°F for the first three days of the illness. When I examined him he still complained of giddiness on attempting to walk, and some pain, though much less than a few days before. There was almost complete left facial paralysis, and the left concha showed an eruption consisting of crusts and drying vesicles and pustules. The meatal skin was somewhat swollen and presented the remains of a similar eruption while the tympanic membrane was grey in colour and desquamating The hearing of the right ear was normal, that of the left very defective In the left ear Rinné's test was positive and much shortened, the sound of a tuning fork on the vertex was referred to the good ear, and bone conduction was greatly diminished.

CASE 2.—A man of 28, sent to the Liverpool Royal Infirmary by Dr G S Swan, of Rock Ferry For ten days he had suffered from right-sided facial palsy (complete at first but now diminishing), vertigo with a tendency to fall and walk to the left, and deafness of the right ear More recently he had noticed a moderate degree of pain about the ear with tenderness and sores on the pinna. Examination showed incomplete right facial paralysis, a few small crusts, apparently the remains of herpetic vesicles, on the pinna an opaque and slightly desquamating tympanic membrane, and almost complete loss of taste on the right side of the tongue. There was also marked nerve deafness of the right ear, a watch being heard on contact only, Rinné's test positive, and bone conduction for a C 128 fork 20 seconds below normal He still complained of some vertigo and showed a tendency to stagger towards the left on attempting to walk with eyes closed.

CASE 3—A woman of 33 had suffered four weeks before I saw her from intense pain in the right side of her face. Three days later she had a sudden attack of vertigo and vomiting and became deaf in the right ear On the following day a vesicular rash appeared on the right side of the forehead and chin and on the right cheek. The neck and pinna were unaffected and facial palsy was completely absent. On examination there was found marked nerve deafness of the right ear with great loss of bone conduction much lowering of the upper tone limit, and relatively good hearing for low tones No trace of eruption was to be seen either on the tympanic membrane, the meatal skin, or the auricle. The vertigo, which had been sufficiently severe to confine the patient to bed for a fortnight, had, when I saw her, almost subsided, leaving only a sensation of unsteadiness. Six weeks later the hearing of the affected ear had undergone much improvement, but still remained somewhat below normal

As already mentioned, Cases 1 and 2 are fairly typical examples of herpes zoster oticus, and it is easy to understand that a case such as the first of these might, on a cursory examination, be mistaken for one of acute otitis media with labyrinth complications An error of this kind is to be avoided by a careful consideration of all the facts, and by bearing in mind the occasional occurrence of Ramsay Hunt's syndrome

The third case, although it was not one of herpetic inflammation of the geniculate ganglion, seemed to me worthy of record because it illustrates an allied condition which is referred to by Ramsay Hunt as herpes facialis with acoustic complications In cases of this sort the principal seat of the herpetic inflammation is in the Gasserian ganglion, to whose zone the eruption is limited, while the absence of facial palsy and of eruption in the zoster zone of the geniculate ganglion suggests that the labyrinth symptoms (deafness and vertigo) are due to herpetic inflammation of the eighth nerve ganglia of Corti and Scarpa, which are to be regarded, like the geniculate, as true posterior root ganglia

---

MANCHESTER HOSPITALS.—At the annual meeting of the Manchester and Salford Hospital for Skin Diseases, held on March 17th, it was stated that the hospital did not receive adequate support from towns outside its own immediate area. During the past year the number of patients from Manchester was only 40 per cent. of the total, and the number from Salford 15 per cent., the remaining 30 per cent. coming from outside towns. From Ashton-under-Lyne there came 788 patients, from Bolton 851, from Oldham 930, from Stretford 1074, and from Stockport 1265 Nearly all the private subscriptions, however, came from Manchester Patients came from 430 towns and villages, but the amount of private subscriptions that came from these towns and villages was very small.—A new nurses home which has cost £15,354 was formally opened on March 17th in connexion with the Hope Hospital, Salford At the hospital the accommodation of all kinds has been more than trebled There are now 238 bedrooms instead of 72, and 25 public and private sitting rooms instead of 5 During the war the nursing staff was 78 in number; now it is 158 Up to 1920 the staff worked 70 and 80 hours a week. They now work an eight-hour day—Owing to the inadequacy of the premises of the Manchester Northern Hospital for Women and Children a public meeting was held on March 16th in support of an appeal for £150 000 to build a new hospital. A site has been given by Sir Edward Holt in Cheetham Hill road What it is proposed to erect is a building which will accommodate 200 beds and cots, for an out-patient department, and a nurses home Up to the present £31,020, which sum includes £10,230 from the general fund, has been subscribed recourse must be had to human skin. The only human individuals possessing skin suitable for the test are those who are sensitive to small amounts of toxin—i.e., those who are classified together in Groups V. and VI. These comprise the bulk of children of junior school age who have not had scarlet fever and a small proportion of ordinary adult males and females. There are many reasons why this large series of tests should not be carried out on children, and we were fortunate in having at our disposal an adult male who was eager that we should use him as much as we should consider necessary. This lucky circumstance we gladly seized upon, as it gave us the opportunity of estimating in a short space of time the antitoxic titre of the 40 sera, and, moreover, it afforded us strictly comparable findings as between one serum and any other throughout the whole series, a result which would have been unattainable had use been made of a number of suitable volunteers.

The whole period taken up by the inoculations occupied 14 days, a batch of five to ten sera being given at one time and followed by one or two days of rest. Readings were taken 24 hours after inoculation, and are recorded as follows :—

+ = a reaction equal to or larger in area than that covered by one skin test dose.

— = no reaction, or a reaction smaller than that caused by one skin test dose.

Except for slight dissociation in the case of the first five sera to be tested, no difficulty was experienced in reading reactions until we reached the last quarter of the series. Then it became apparent that the individual whom we were inoculating was reacting to some constituent of the toxin other than the toxin itself. A series of tests showed him to be sensitive to rabbit serum and also to some ingredient of the condensation water taken from salt agar tubes which contained no peptone or meat extract. The combination of these two factors resulted in the production of what may be termed a pseudo-reaction which tended to mask the negative reactions and also to emphasise the positive ones. It would appear, therefore, that an increased susceptibility to a pseudo-reaction must be borne in mind in interpreting the results of a large series of inoculations in any one individual. In this particular instance the reactions obtained at the end of the series were still readable, though with difficulty, and we do not feel that the individual could be profitably used for further injections of a similar character until he has lost his sensitiveness.

### *Results.*

The findings in respect of the reactions in individual scarlet and non-scarlet children are set out in Tables A and B respectively. The results show that the differentiation between these two groups in regard to their antitoxin content is as follows :—

1. If the unit of antitoxin be taken as that amount which gives complete neutralisation of one skin test dose, then out of 20 scarlet fever children 17 were found to yield a serum which contained 50 units or more of antitoxin, whereas of the non-scarlet children only eight reached this titre. 2. Of the 20 scarlet children nine yielded a serum containing 125 units or more, whereas only three of the non-scarlet children did so. 3. # HERPES ZOSTER OTICUS AND ALLIED CONDITIONS,

WITH NOTES OF THREE CASES.

By THOMAS GUTHRIE, M.B., B.C. Camb., F.R.C.S. Eng.,

HON. LARYNGOLOGIST TO THE LIVERPOOL ROYAL INFIRMARY; HON. LECTURER IN LARYNGOLOGY, LIVERPOOL UNIVERSITY.

Herpes zoster of the skin of the auricle was described and figured many years ago. In the second edition of Gruber's book on the ear, published in 1890, mention is made of its association with nerve deafness, while Politzer, in the fourth edition of his text-book (1902), refers to facial palsy as yet another feature of some of these cases. But the credit for the first complete description of the interesting syndrome, known to-day as herpes zoster oticus, is due to J. Ramsay Hunt, to whose writings I am indebted for much of what follows. In 1907 and 1908 he gave a detailed account of the disease and its complications based on four cases observed by himself, together with 56 others collected from the literature.

It is well known that herpes zoster affecting an area on the trunk or limbs is due to an inflammation of one or more of the ganglia of the posterior or sensory roots of the spinal nerves. These ganglia contain cells of the unipolar type, and with the sensory or afferent portion of certain of the cranial nerves are associated ganglia containing similar unipolar cells, and clearly representing posterior root ganglia. One of these is the geniculate ganglion of the facial nerve. This ganglion receives its afferent fibres from the sensory portion of the nerve which consists not only of the chorda tympani, but also of fibres from a certain well-defined area of skin. These are incorporated in the auriculo-temporal branch of the third division of the fifth nerve and in the auricular branch of the vagus, and reach the ganglion through its connexions with these nerves.

The area of skin affected by herpetic inflammation of the geniculate ganglion is intercalated between the areas affected in herpes occipito-collaris and in herpes facialis, which are due respectively to disease of the upper cervical and of the Gasserian ganglia. The vesicular eruption is limited to "a cone-shaped area with its apex on the tympanic membrane and its base of the auricle" (Hunt), consisting of the tympanic membrane, external auditory meatus, concha, tragus, antitragus, lobe (outer surface), antihelix, and fossa antihelicis.

As the motor fibres of the facial nerve are closely applied to the ganglion the inflammatory process readily spreads to these, and the result is facial paralysis, which was noted in all the cases of herpes zoster oticus collected by Ramsay Hunt. Often the inflammation extends further and affects both the cochlear and the vestibular portions of the eighth nerve, causing nerve deafness, tinnitus, vertigo, and vomiting. This occurred in 19 of Hunt's cases. Moreover, just as in herpetic inflammation of the spinal ganglia, while one ganglion is chiefly affected, those on either side of it tend to suffer in a less degree, so in certain cases, presenting some or all of the ordinary features of geniculate ganglion disease, there may be also indications of coincident herpetic inflammation of other ganglia, such as the Gasserian or the second, third, and fourth spinal ganglia. It is probable indeed that occasionally the eighth nerve ganglia of Corti and Scarpa are *directly* affected, since these ganglia are developmentally homologous with posterior root ganglia. The resulting symptoms (deafness, vertigo, &c.) will then be clinically indistinguishable from those met with in typical cases of herpes zoster oticus in which the *trunk* of the eighth nerve is affected by inflammation spreading from the geniculate ganglion. In this way are probably to be explained certain cases of herpes occipito-collaris and herpes facialis with eighth nerve symptoms, but without geniculate ganglion involvement.

Herpes zoster oticus is a rare condition. It is met with in about 1 in 20,000 cases of ear disease. Pain about the pinna and mastoid region may be severe and may be present for two or three days before the eruption appears. It was the first symptom in one of my cases, and in another was preceded by the vertigo. It is sometimes present also in the distribution of the upper cervical and the fifth nerves, due to coincident inflammation of the corresponding ganglia, or in the case of the fifth nerve to its connexion with the geniculate ganglion through the great and small superficial petrosal nerves.

As the eruption affects the tympanic membrane and skin of the meatus as well as the pinna, there may be, two or three days after it has appeared, much inflammatory swelling of the meatal walls with otorrhœa and sometimes secondary swelling of the mastoid lymphatic gland. These appearances, together with the intense pain, deafness, facial palsy, and sometimes pyrexia, are very suggestive of acute otitis media with mastoiditis, for which cases of herpes zoster oticus are occasionally mistaken. Points of importance in the diagnosis are (1) the nature and distribution of the eruption; (2) the type of the deafness—namely, inner- and not middle-ear deafness; (3) loss of taste in the corresponding side of the tongue, owing to affection of the chorda tympani nerve; (4) absence of perforation of the tympanic membrane, although its appearance may be much altered by the eruption, and, in any case, an intact drum does not of course exclude disease of the *middle* ear.

The duration of the disease varies considerably. Some degree of neuralgic pain usually persists for two or three weeks. The facial paralysis may be evanescent, lasting only a few days, or it may disappear gradually during the course of some weeks. The same applies to the deafness and other symptoms of eighth nerve involvement. In rare cases some degree of facial palsy and nerve deafness is permanent.

Treatment consists of sedatives for the pain, the usual local applications for the herpetic eruption, and massage and electrical treatment for the paralysis if this persists.

## *Clinical Records.*

The following are brief notes of three cases which I have observed, the first two being characteristic examples of herpes zoster oticus, and the third a case of herpes facialis with eighth nerve symptoms.

CASE 1.—A man, aged 56, whom I saw at the request of Dr. John Hay, was in bed suffering from vertigo and vomiting, which began ten days before I saw him. For eight days there had been pain in and about the left ear and a vesicular eruption had developed on the pinna. Three or four days after the onset of the pain left facial palsy had appeared His temperature had varied between normal and 102°F. for the first three days of the illness. When I examined him he still complained of giddiness on attempting to walk, and some pain, though much less than a few days before. There was almost complete left facial paralysis, and the left concha showed an eruption consisting of crusts and drying vesicles and pustules. The meatal skin was somewhat swollen and presented the remains of a similar eruption, while the tympanic membrane was grey in colour and desquamating The hearing of the right ear was normal, that of the left very defective. In the left ear Rinné's test was positive and much shortened, the sound of a tuning fork on the vertex was referred to the good ear, and bone conduction was greatly diminished.

CASE 2.—A man of 28, sent to the Liverpool Royal Infirmary by Dr G S. Swan, of Rock Ferry For ten days he had suffered from right-sided facial palsy (complete at first but now diminishing), vertigo with a tendency to fall and walk to the left, and deafness of the right ear More recently he had noticed a moderate degree of pain about the ear, with tenderness and "sores" on the pinna. Examination showed incomplete right facial paralysis, a few small crusts, apparently the remains of herpetic vesicles, on the pinna, an opaque and slightly desquamating tympanic membrane, and almost complete loss of taste on the right side of the tongue. There was also marked nerve deafness of the right ear, a watch being heard on contact only, Rinné's test positive, and bone conduction for a C 128 fork 20 seconds below normal He still complained of some vertigo and showed a tendency to stagger towards the left on attempting to walk with eyes closed

CASE 3—A woman of 33 had suffered four weeks before I saw her from intense pain in the right side of her face. Three days later she had a sudden attack of vertigo and vomiting and became deaf in the right ear. On the following day a vesicular rash appeared on the right side of the forehead and chin and on the right cheek. The neck and pinna were unaffected and facial palsy was completely absent. On examination there was found marked nerve deafness of the right ear with great loss of bone conduction, much lowering of the upper tone limit, and relatively good hearing for low tones. No trace of eruption was to be seen either on the tympanic membrane, the meatal skin, or the auricle The vertigo, which had been sufficiently severe to confine the patient to bed for a fortnight, had, when I saw her, almost subsided, leaving only a sensation of unsteadiness. Six weeks later the hearing of the affected ear had undergone much improvement, but still remained somewhat below normal

As already mentioned, Cases 1 and 2 are fairly typical examples of herpes zoster oticus, and it is easy to understand that a case such as the first of these might, on a cursory examination, be mistaken for one of acute otitis media with labyrinth complications. An error of this kind is to be avoided by a careful consideration of all the facts, and by bearing in mind the occasional occurrence of Ramsay Hunt's syndrome.

The third case, although it was not one of herpetic inflammation of the geniculate ganglion, seemed to me worthy of record because it illustrates an allied condition which is referred to by Ramsay Hunt as herpes facialis with acoustic complications. In cases of this sort the principal seat of the herpetic inflammation is in the Gasserian ganglion, to whose zone the eruption is limited, while the absence of facial palsy and of eruption in the zoster zone of the geniculate ganglion suggests that the labyrinth symptoms (deafness and vertigo) are due to herpetic inflammation of the eighth nerve ganglia of Corti and Scarpa, which are to be regarded, like the geniculate, as true posterior root ganglia.

### SECTION OF MEDICINE.

A meeting of this Section took place on March 23rd, Dr. Hugh Thursfield, the President of the Section, occupying the chair.

### Modern Methods of Controlling Infectious Disease.

Sir John Robertson (Birmingham) read a paper on this subject, which was supplemented by charts and diagrams. His purpose, he said, was to deal with certain general principles, leaving matters of detail aside. Some of the newer methods for controlling these diseases had been but little tried, and hence were not yet ripe for general discussion. No two infectious diseases could be successfully dealt with, from the preventive standpoint, by identical methods, but there was a tendency towards a different belief. The better the knowledge of the natural history of a disease the more efficient was its control likely to be. And the present higher standard of intelligence in the general community on these subjects was a favourable factor in keeping down infectious disease. The mortality from various infectious diseases in this country had shown an enormous decline; the small-pox mortality had practically vanished, enteric fever in most districts was practically unknown, so that it was difficult to get a case of it to demonstrate to students, while the mortality of scarlet fever was now a vanishing quantity. In regard to the incidence of the last named, however, there appeared to be very little reduction, though there were a number of factors which militated against correct incidence figures being obtained. The diphtheria mortality curve had gone down very much indeed. Measles showed a fairly high mortality in the first 25 years of the half century, but since then the mortality had gone down. Whooping-cough had not had special means of control applied to it, yet the mortality had gone down in a wonderful way. Also the death-rate of the composite condition classed as bronchitis had largely declined. Pneumonia, on the other hand, showed little reduction in mortality. The acute condition influenza did not seem to have been checked by any control measures. As to possible causes for the improved returns in most of the diseases, he did not doubt that the type of disease was now milder, and because of that all the cases might not have been diagnosed. The rate of infection among young children could not now be so great as formerly because the proportion of young children in any British population was now less than 50 years ago. Of every 1000 population in 1871, 361 were children under 15 years of age, whereas in 1921 there were only 277 children under 15, a difference of 84 per 1000.

In the past, four methods had been applied in the attempts to control infectious diseases—notification, isolation, quarantine, and disinfection. Within recent years to these had been added immunology. Each disease responded in a different way. The best results ever obtained in the prevention of any infectious disease were those which followed the active immunity caused by vaccination against small-pox. But when only 30 per cent. of the population were vaccinated and a number were but imperfectly protected by vaccination it was necessary to bring into operation isolation and quarantine. These were very satisfactory if carried out with intelligence and vigour. The difficulty at present was that a number of cases of small-pox were so mild that they escaped notification. There appeared to be very little immunity in small-pox—i.e., few unprotected people escaped the disease when exposed to the infection. The virus of small-pox was easily killed by exposure to light and air, but was capable of remaining virulent a long time when shut into an enclosed space. In this connexion he related the [illegible] which a book belonging to a small-pox patient (who died) was handed round to relatives 13 months later, and the disease then broke out in three separate houses into which the book was taken. Scarlet fever was in a different category in regard to immunity, for natural immunity played a definite part in limiting the number of cases, and Sir John Robertson considered it also had much to do with reducing its virulence. If perfect bed isolation could be ensured he thought scarlet fever could be treated in the wards of a general hospital without fear of infecting other patients. The "Dick" positives numbered 70 per cent. in young children, and the proportion gradually fell with advancing years, until at 20 years it was only 11 per cent. Among adults who had had the disease earlier in life only 3·9 per cent. were Dick-positive. With regard to the active immunisation of people against scarlet fever, experience was not yet sufficient to warrant its general use as a preventive measure. Much good work was, however, being done in this direction, and he did not doubt it would be possible for any medical practitioner at a future date to protect any individual against an attack of scarlet fever. Isolation had not limited the spread of the disease; indeed, as a means of control, isolation was of little value to the community. Still, it was a great convenience and of value to the public. The disadvantage was that, unless the discipline in the fever hospital was really good, the patients were apt to contract from other patients infections other than their own. The proportion of immune persons was largest where the population was densest, and the explanation was considered to be that they were gradually immunised by the widespread infection. Certainly spread of the disease was most rapid in sparsely populated areas. It was not yet sufficiently realised that nose, throat and ear secretions were a potent source of infection. In Birmingham the mortality from scarlet fever was now 1·09 per cent. At present reliance was placed on the old methods of isolation and disinfection, but there was reason to hope that the work now being done on the subject would produce a satisfactory method of limiting, by immunisation, the incidence of this disease.

In regard to diphtheria, hospital disinfection and isolation had apparently accomplished nothing in reducing the incidence rate, but in Britain the mortality had been greatly reduced; 30 years ago it was 30 per cent. in Birmingham, now the figure was about 5 per cent. The most severe cases of diphtheria should be removed to hospital for skilled medical supervision and nursing, though not with the expectation of preventing the spread of the disease. This spread was brought about by carriers, who could be divided into virulent and non-virulent. The virulent were further divisible into those who were carriers for a short time and those who could be regarded as chronic carriers, many of whom had diseased tonsils, often in association with adenoids. The laryngologist's aid should be sought for these. Some people seemed to have a natural immunity against diphtheria. New York statistics gave 93 per cent. of positive Schick reactions among infants under 1 year, and here again, as in scarlet fever, there was a progressive diminution in the proportion of positives as age advanced. Active immunisation of young children would probably reduce the incidence of diphtheria practically to nil. The immunisation of 38,000 in America reduced the deaths from 1500 per annum to 663. The use of a toxoid plus antitoxin would protect a child, certainly past its period of greatest danger. It was now a safe method, and it reduced the risk of infection by about 70 to 90 per cent. The difficulty associated with the use of the immunisation method in this country was the rooted objection of the people to inoculations of any kind.

Tuberculosis showed a great reduction in mortality, and in the areas where propaganda work was active the incidence rate of the disease had fallen wonderfully. In Birmingham it was now half what it was 10 or 15 years ago. Concerning measles, little had been done in the way of preventing outbreaks of this disease from spreading. In Paris a system of immunising children in public dispensaries had given, according to the claims of the staff, very fine results. Isolation had probably been of some help in the enteric group of diseases, but he attributed the diminution mainly to mass sanitary measures, such as the provision of uncontaminated water, the removal and destruction of refuse heaps, &c. He raised the question whether a general cause was not at work, such as a gradual immunisation of the people, to account for the milder type of diseases, the lowered mortality, and, in many instances, the lessened incidence rate. Disinfection of rooms inhabited by patients by burning sulphur or by liberating chlorine gas was no longer necessary; if everything used and the room were thoroughly cleansed nothing further seemed to be called for.

### *Discussion.*

Dr. C. R. **BOX** agreed that there were no stereotyped methods applicable to the prevention of all infectious diseases. It was only by increasing knowledge of the nature and cause of disease and the manner of its spread, as well as of the problems of bodily defence, that success in this campaign could be hoped for. This success would be greatly helped by the spread of knowledge among the general public, and it would materially lessen their objection to inoculations. He suggested that immunity was set up by a heavy dose of infection calling forth the defensive mechanism of the body. He considered that the scarlatinal carrier was a very important person. Sir John Broadbent had recorded the case of a boy who had no symptoms, but who left scarlet fever in his wake wherever he went. The infection in this disease, he agreed, was spread by discharges from the ear, nose and throat.

Dr. E. W. **GOODALL** said that to talk of controlling infectious disease was to speak loosely. One did not control the disease; what were controlled were the actions and the circumstances surrounding the sufferer from the disease. Efforts, proved to be futile, had been directed against the micro-organism, to the neglect of other methods, for there was a tendency to consider not only that the microbe was the cause of the disease, but that it was the disease itself. Only in the case of diphtheria had the mortality been diminished by therapeutic measures. In regard to the death-rate from pneumonia and influenza there was little cause for satisfaction. The decrease in the scarlet fever mortality he attributed to a lessened virulence. He pleaded for a continuous close study of the natural history of these diseases as affording the most hope for improvement, as bacteriology had not been of so much help as was expected. Of all the measures adopted he thought the most important was that of rendering ourselves immune from attack. In the case of measles, this had not been done in England by obtaining blood serum from the measles patient, and it might prove a somewhat formidable proposition, seeing that it required the serum of about 300 children to immunise 2000 to 3000 children. Vaccination against small-pox was largely falling into abeyance, and the hopes in regard to protection by immunisation on a large scale were not at all bright. The toxin-antitoxin method, applied on a small scale, had been shown to be of great value.

Dr. R. A. **O'BRIEN** directed attention briefly to a discussion of controlled and uncontrolled immunisation in diphtheria. He said that he and his colleagues had had under observation, in four years, three residential institutions in which a good deal of diphtheria had occurred. All the children were tested and immunised, and kept immunised, and during those four years there had been no case of clinical diphtheria among them, though they were exposed to the risks of infection. In one school there was a large outbreak of the disease, a case of uncontrolled incidence. This was followed by a period of immunity, and it had been found that the importation of fresh residents was a menace unless they were subjected to the same process. He considered that efforts should be made to immunise the nursing and other staffs of the fever hospitals of the country, as the dislocation of duties through illness was a serious matter, besides being a source of economic loss.

Major G. S. **PARKINSON**, R.A.M.C., spoke of the experiences in relation to infectious disease during the war, and the effective way in which typhoid was checked by inoculations. At one period in the early stages of the war the supply of antitetanic serum gave out, and the incidence rate of that disease at once rose, to be as quickly brought down when a fresh supply arrived. During a campaign the men were under strict control, hence results could be very definitely ascertained, whereas in civil life public opinion was often an obstacle to efficient control and treatment. Gibraltar afforded a good example of control. Everyone there was vaccinated against small-pox, and no case of that disease occurred there, though it was prevalent in Spain and Morocco, countries with which Gibraltar was in constant communication.

The **PRESIDENT** thought the idea of a general pool of acquired immunity was a possible explanation of the fall in the death-rate, and to a large extent of the incidence rate, too, of many infectious diseases, in which influenza did not share. A further point concerned the fall in the incidence and the death-rate from the conditions classed by the Registrar-General as bronchitis. This was largely due to better general social conditions, and especially to regulations applied to factories by the Home Office. As an instance he could recall large numbers of cases of bronchitis coming to St. Bartholomew's Hospital from the brass-works of Clerkenwell, but since the Home Office Regulations had been in force the number of these had been very much less.

## SECTION OF EPIDEMIOLOGY AND STATE MEDICINE.

AT a meeting of this Section held on March 26th, Dr. E. W. **GOODALL** in the chair, Prof. W. J. **WILSON** read a paper on

### *Typhoid Fever in Northern Ireland.*

He began by calling attention to the great reduction of mortality from typhoid fever which had taken place, not only in the United Kingdom but in most European countries. In 1875 the rate of mortality from typhoid fever in Ireland was lower than in England and Wales; it was 1·6 per 10,000 as compared with 3·7. Between 1875 and 1886 the rate declined in England and Wales but was almost stationary in Ireland; the rates in 1886 were 1·8 in England and 1·6 in Ireland. Little change occurred in the next ten years, but since 1900 there had been a considerable decline, greater in England than in Ireland; in 1924 the rates were 0·13 for England and Wales and 0·31 for Ireland. Prof. Wilson pointed out that in Ireland the rural population was relatively much more numerous than in England and that the development of the creamery system, together with imperfect public health control, had been responsible for several outbreaks in rural areas. Passing to the special problems of Belfast, he presented statistics showing the great decline of typhoid fever in that city. The mortality-rate was 7·0 per 10,000 in 1872–75 and as high as 9·7 in 1896–1900. Since 1910 it had never reached 1·0 and in 1924 it was only 0·07. He referred to the late Dr. L. W. Darra Mair's report incriminating shell-fish, and, while expressing his admiration of that report and his belief that much typhoid in Belfast had been due to the consumption of contaminated cockles and mus[illegible] did not think that the great decrease of recent [illegible] could be attributed wholly to a change of habit in [illegible] use of shell-fish. He attached much importan[illegible] the abolition of privies, the substitution of [illegible] ashpits, improved scavenging, abatement of [illegible] decrease of stables and byres with their [illegible] flies, more effective sanitary admini[illegible] standard of living and education, and [illegible] a sanitary conscience. The work of [illegible] Taylor on the effect of the addi[illegible] [illegible] to an infected populat[illegible] a [illegible] in the Belfast ex[illegible] mortality had been during the [illegible] expansion, when the increase of population was due not merely to excess of births over deaths but also to immigration. Prof. Wilson concluded his paper with an account of a series of outbreaks which had been fully studied.

His paper was discussed by Sir William Hamer, Sir George Buchanan, Dr. Major Greenwood, Dr. S. Monckton Copeman, Dr. G. C. Trotter, Dr. J. A. Arkwright, Fleet-Surgeon W. E. Home, and Dr. Goodall.

## LONDON ASSOCIATION OF MEDICAL WOMEN'S FEDERATION.

A meeting was held on March 9th, Dr. Christine Murrell, the President, being in the chair, when Miss Gertrude Herzfeld gave an address on the

### *Acute Abdomen in Childhood.*

She spoke first of the differences between the pathology of this condition in adults and in children. In children the lesions were limited to the embryological mid-gut, corresponding to the small intestine and the first two-thirds of the large intestine. As to the manifestations of inflammatory or obstructive conditions, these were much more speedily noticeable in children. Inflammation proceeded to suppuration much more rapidly and obstruction soon gave rise to symptoms of toxæmia. For these reasons the practitioner should not wait to make a differential diagnosis once he was convinced of the presence of an acute condition in the abdomen, but should at once call in surgical aid. Prior to laparotomy the child should be kept warm and given plenty of fluid; subcutaneous saline injections should be administered if there had been much vomiting. It was the speaker's custom to give atropine in large doses, gr. 1/200 to 1/150, to infants under 2 before operation, and gr. 1/100 to children over 2. Warmth in the theatre, speed in operating, and gentle handling were essential to success. Only two incisions were used by her—the gridiron incision, where appendicitis or an intussusception proximal to the transverse colon was suspected, otherwise a vertical paramedian incision. Post-operative saline infusions were always given.

The conditions giving rise to an acute abdomen in childhood could be divided into inflammations and obstructions. Among the former, appendicitis (50 per cent. of all abdominal cases), pneumococcal peritonitis, streptococcal peritonitis, Meckel's diverticulitis, and tuberculous abdomen had to be considered. Congenital obstructions to be looked for included imperforate anus, congenital hypertrophy of pylorus, maldevelopment of gut, bands, and Meckel's diverticulum. Acquired obstructions might be due to intussusception (20 per cent. of abdominal cases in childhood), tuberculous peritonitis, hernia, or volvulus. She discussed in some detail acute appendicitis and intussusception as being relatively common conditions, and gave an account of recent investigations into the rare condition of pneumococcal peritonitis.

*Acute appendicitis* could occur at any age, but generally the patient was over 2 years. It was rarely diagnosed before suppuration supervened; over 90 per cent. of Miss Herzfeld's cases were already suppurating at operation. She had found pus as early as within 12 hours of the first attack. Vomiting was almost invariable except where the appendix was in the pelvis, in which case pain might be localised at the umbilicus in the young child, or in the suprapubic region in the older one. There might be frequent and painful micturition through involvement of the bladder, or diarrhœa. There was little rigidity of the abdominal wall, but on rectal examination tenderness was found not only during insertion of the finger, which was usual in normal children, but on movement of the finger-tip in certain directions. The feature of [illegible] of a retrocæcal appendix was a lack of [illegible] the abdomen associated with posterior [illegible] of the lumbar muscles; vomiting might occur. If the appendix was associated with an undescended cæcum the rigidity and tenderness were to be found higher up in the abdomen.

The differential diagnosis of appendicitis from diaphragmatic pleurisy and pleuro-pneumonia could be very difficult. In the last-named condition the rigidity and tenderness were not so well marked nor so persistent as in appendicitis. Sometimes re-examination some 20 minutes after the first examination revealed a shifting of the signs to another place. The general appearance of a child with pneumonia was characteristic. Acute and subacute pyelitis could be differentiated from appendicitis by a microscopic examination of the urine, which was usually acid, and by the presence of lumbar tenderness. In ileo-cæcal tuberculosis abdominal tenderness was very marked, but rigidity less so, and the child, on the whole, was not so ill. This condition might be very difficult to differentiate from appendicitis and in doubtful cases it was better to explore. The possibility of cyclic vomiting must be borne in mind and excluded, since an anæsthetic was injurious in this condition. The history of vomiting previous to the attack and the presence of acetonuria were diagnostic features.

*Pneumococcal peritonitis* was a rare condition, but the mortality was high (70 to 75 per cent.) irrespective of treatment; it could be primary (so-called idiopathic) or secondary to pneumonia or some other lesion. The primary form was of especial interest, as its pathology had only been worked out by Prof. J. Fraser and Dr. J. E. Macartney of recent years in Edinburgh. It occurred only in little girls of the hospital class, the average age being 5½. It began as a pelvic peritonitis and was an ascending infection, through the vagina, in children who had a vaginal discharge. The class incidence might be accounted for by the inadequate clothing and the habit, among the poorer children, of sitting on dirty steps. A septicæmia rapidly followed the peritonitis, with a positive blood culture in 6 to 12 hours. Experimental work on rabbits had enabled the course of infection to be traced and had proved that the blood infection was a secondary one. The child suddenly complained of acute abdominal pain, followed by vomiting, delirium, and high temperature. In the less acute cases the septicæmia might be delayed for 48 hours. The only possible treatment was drainage of the lower abdomen. Blood transfusion had not proved of much avail.

*Intussusception.*—The typical features were onset of acute abdominal pain in a fat, strong, healthy baby, usually a boy, over 4 months of age. The usual history was that the child screamed and drew up his legs, then "fainted away," and, exhausted, fell asleep, only to awake half an hour later with another attack; vomiting would begin at this stage, and sooner or later blood would be passed per rectum. Since the contents of the bowel distal to the ileo-cæcal region had first to be emptied, blood was not necessarily passed at once. Miss Herzfeld quoted cases to show the difficulty of diagnosis even when blood was passed. It was unwise to operate unless the tumours could actually be felt under anæsthesia. If the patient was under a year old reduction alone should be performed at operation, for any mutilation at the time was not well borne by the infant.

Dr. Hazel Gregory pointed out that in children rigors, if present, were pathognomonic of acute *B. coli* pyelitis.

Miss L. Martindale described a fatal case of pneumococcal peritonitis in a child of 5. The child was not of the hospital class, but had previously been brought for advice for vaginal discharge and masturbation.

## LONDON CLINICAL SOCIETY.

This Society held a clinical evening at the London Temperance Hospital on March 18th, Mr. Herbert J. Paterson, the President, in the chair.

The President showed a man who is undergoing a series of plastic operations to replace a nose destroyed by lupus. He also showed a series of radiograms illustrating an unusual site for gastric ulcer, where the clinical diagnosis was only confirmed by taking lateral views after antero-posterior exposures had proved negative.

Dr. FLEETWOOD WALKER showed a man who two days before, on the advice of a friend, had taken a teaspoonful (repeated four hours later) of the following mixture to cure a cough: 1 eggcupful of resin powdered, 1 eggcupful of honey, 2 tablespoonfuls of vinegar. On taking the second dose he came out in a generalised punctate scarlatiniform rash which still persisted. On the following morning his face was puffed. The urine showed the presence of resinous bodies when treated with nitric acid.

Mr. H. P. WINSBURY WHITE showed: (1) A colour drawing of malignant disease of the kidney. (2) A specimen of kidney with large stone (with X ray photographs by Mr. J. C. Macduff). The chief interest in the case was that the patient had for several years had renal symptoms on the opposite side, which had helped to mask the diagnosis. (3) Specimens of large stones removed from the bladder of a woman, aged 32, who had had two Cæsarean sections. The patient had also passed ligatures per urethram. During the discussion Mr. White said that he would give no expression of opinion as to whether catgut ligatures should be used in Cæsarean sections, although aware that over 90 per cent. of cases of ruptured uterus occurred in cases in which catgut had been used.

Dr. HAROLD SANGUINETTI showed: (1) A specimen of a strangulated inguinal hernia from an infant aged 4 months. The child was admitted to hospital as a case of broncho-pneumonia and died after a few hours. The condition was only found on post-mortem examination. (2) A specimen of stenosis of the duodenum in an infant. The child was admitted to hospital because the mother said it was not passing any urine. The condition was discovered post mortem. (3) A specimen of kidneys, ureters, and bladder in a case of bilateral renal calculi in a woman who developed bacilluria after an operation for carcinoma of the breast.

Dr. PHILIP FIGDOR showed a single woman, aged 28, who had complained of stiffness and pain in the left knee, which had commenced one month after she knocked her knee against an iron bar in October last. The knee was swollen, the synovial fluid was increased, and all movements were painful. She gave a history of night sweats for the past four months and also a strong tuberculous family history. The X rays showed some indefinite patellar changes. The intradermal tuberculin test was strongly positive, while the Wassermann was also strongly positive. The case was probably one of syphilitic arthritis. She was having auto-syphilitic treatment as well as ionisation locally.

---

## MANCHESTER MEDICAL SOCIETY AND LIVERPOOL MEDICAL INSTITUTION.

AT a joint meeting of the Manchester Medical Society and Liverpool Medical Institution held at Manchester on March 3rd, Prof. A. H. BURGESS, the President of the Manchester Medical Society, took the chair, and Mr. R. C. DUN (Liverpool) read a paper on

### *Chronic Intussusception.*

This condition, he said, was much less common than acute intussusception; it occurred in older children, and there was a larger proportion of the enteric and colic forms; the sexes were equally affected. The symptoms were slight, indefinite, intermittent, and prolonged. In his 13 cases they had been present for periods ranging from four weeks up to two and a half years. Umbilical pain was usually slight and collicky; vomiting was occasional and concurrent with the attacks of pain; constipation was not marked, and there was always a deterioration in health. An abdominal tumour was felt in 9 out of the 13 cases; it was intermittently present, appearing and disappearing with the pain, and in two cases only was it long enough to be called sausage-shaped. Blood and mucus in the stools was only noticed in two of the cases, and in both of these it was intermittent. Diagnosis was difficult owing to the evanescence of the abdominal tumour, and it was important to make frequent examinations, especially during the attacks of pain, so as not to miss this sign. In no case had the intussusception progressed far enough to cause acute intestinal obstruction.

The treatment, said Mr. Dun, had been laparotomy and reduction in all cases. This had always been easy; no adhesions had ever been found, and there had been practically no œdema. In none of his 13 cases did the symptoms recur after operation. No obvious pathological condition had been met with in any of the cases which could account for the intussusception.

### *Cysts of the Semilunar Cartilage.*

Mr. T. P. MCMURRAY (Liverpool) reported eight cases. Unlike those previously reported, three of them were in connexion with the internal semilunar cartilage; the 18 cases previously reported had all been associated with the external cartilage. The cysts were multilocular, contained clear fluid, and required excision for the cure of the symptoms. Two of them had already been operated on by other surgeons, when the cysts alone had been removed with no relief of the symptoms. In all the eight cases the affected cartilage was removed with the cyst and a complete cure resulted. Microscopical examination of the cyst wall showed that it was lined with compressed cartilage cells and intercellular strands with darkly staining nuclei, but no trace of endothelium or epithelium. Blood-vessels were seen on the outside of the cysts, but not to the same extent as between the cysts. From the presence and from the position of the blood-vessels connected with the cysts, it was concluded that the cysts were traumatic in origin, and of the nature of degenerate change.

### *The Purgative Action of Magnesium Salts.*

Dr. HENRY COHEN (Liverpool), who read a paper on this subject, pointed out that there were two main theories about the mode of action of the saline purgatives. The first was that their action is entirely local—*i.e.*, exerted solely from the lumen of the intestine. The second was, on the contrary, that the saline purgatives do not act from the lumen of the gut, but only after the absorption of the cathartic ion. The evidence adduced in favour of one or other theory had, up to the present, been too conflicting to justify definite conclusions. Using a special method for the estimation of magnesium in small quantities of serum, Dr. Cohen found that the oral administration of purgative doses of $MgSO_4$ (20–30 g.) was—within the limits of experimental error—unaccompanied by any alteration in the magnesium content of the serum. On the other hand, intramuscular injection of magnesium sulphate in solution (18–20 c.cm. of 10 per cent. aqueous solution) was followed by considerable increase (50–100 per cent.) in the magnesium content of the serum; but in no case was this rise accompanied by the characteristic purgative effect of the salt when given by the mouth. Following a purgative dose of $MgCl_2$ there was a rise in the magnesium content of the serum. This rise was, however, no higher and no less rapid than that following intramuscular injection of $MgSO_4$. Since the latter did not cause purgation, it followed that the purgative action of magnesium salts was exerted independently of the absorption of magnesium into the blood. Dr. Cohen exhibited radiograms showing that, in the same individual, a purgative dose of magnesium sulphate increased the rate of passage of an opaque meal along the intestine and also the bulk of the intestinal contents. Moreover, when the lower bowel was empty before the experiment, the first stool passed after administration of the purgative salt contained bismuth. Dr. Cohen concluded from the two sets of data he had presented that the purgative action of magnesium salts is entirely local and is independent of the absorption of magnesium into the blood stream.

## LIVERPOOL MEDICAL INSTITUTION.

AT a meeting of this Institution on March 18th Mr. G. C. E. SIMPSON read a paper on

### *Acute Appendicitis.*

From the Registrar-General's reports, checked by his knowledge of a small town where he could trace most of the cases of acute appendicitis in the last five years, he had come to the conclusion that the incidence of the disease was about 1 case per 1000 of population per annum, with a mortality in cases treated surgically of about 6 per cent. Cases treated throughout on medical lines (Osler's Medicine, 1901) had a mortality of 14 per cent. He suggested that this would be reduced to less than half if the general peritonitis and abscess cases were submitted to immediate operation and the rest treated on medical lines. The present mortality of the surgical treatment was too high, and the careful choice of the time of operation in later cases would give a reduction, apart from the reduction to be effected by earlier diagnosis. Mr. Simpson quoted from recent writings of Sherren and Adams in favour of delay, and of Burgess and Grey Turner in favour of immediate operation. He professed himself a follower of the St. Thomas's School. Operating at once on all cases seen in the first two days, on cases seen later which were advancing, and as a rule in all children, he used the Ochsner method in doubtful or subsiding cases seen on the third day or later, and operated when they had subsided; these cases, however, must be kept under close observation, and interference undertaken at once if signs of progression were seen.

On these lines Mr. Simpson's mortality in the Northern Hospital in the last five years was only 2·5 per cent. Adding the figures from the cottage hospital in the small town referred to, it was 3·5 per cent. (and in that town the main mortality was in the first year). In the 15 per cent. of his cases in which delay was practised (45 in all) only six failed to settle. (In five abscess required opening, and in one gangrene caused the advance.) And at the subsequent operation no drain was used in 33, although in several there were signs of gangrene, perforation, or abscess, and, in a few, fistula into the intestine. No case died, but in one of the cases of acute abscess a fistula required treatment. Four other cases operated on by Mr. Simpson had fistulæ, and in all of them tubercle was present. Mesenteric or peritoneal tubercle was marked in 5 per cent. of the cases and caseating glands were removed in a number. One case with tuberculous appendicitis and glands died of tuberculous pneumonia.

Mr. Simpson concluded that the mortality of acute appendicitis could be lowered by judicious choice of the time to operate in cases not seen before the third day, but emphasised the need for the cases to be under strict observation and regulation. He considered that this would lead to all suspect cases of appendicitis being kept in the Fowler position and on water only while waiting the advent of the surgeon, and that this, and the opportunities given to students to see more of the symptoms of appendicitis through these cases being detained in the wards, would more than neutralise the ill-effects anticipated by Burgess and Grey Turner from some doctors carrying out the treatment in the wrong cases and under wrong conditions.

Dr. C. RUNDLE read a paper on the use of indicator reactions in diphtheria and scarlet fever.

*Corrigendum.*—In the agenda and report of the discussion on cancer held by the Society of Medical Officers of Health on [illegible] Dr. W. D. Newcomb, pathologist to St. Mary's [illegible] described as assistant pathologist.

# Reviews and Notices of Books.

### TUBERCULOUS DISEASE OF THE HIP-JOINT.

Diagnosis, Treatment, and End-Results. By GEORGE PERKINS, M.Ch. Oxon., F.R.C.S. Eng., Assistant Surgeon to the Royal National Orthopædic Hospital; Orthopædic Registrar, St. Thomas's Hospital. London: Humphrey Milford, Oxford University Press. 1926. Pp. 118. 6s.

IN 1924 the British Orthopædic Association founded the Robert Jones prize and medal, the subject chosen for the first competitive essay being the Diagnosis, Treatment, and End-results of Tuberculous Disease of the Hip-joint. The successful monograph, by Mr. George Perkins, is now published under the auspices of the Association, and it may therefore be regarded as expressing, perhaps more accurately than any work yet issued, the trend of British surgery in regard to this often seriously crippling disease.

Early diagnosis, as might be expected, is dealt with in considerable detail, and the importance of a limp as the primary symptom is very properly emphasised. Stress is laid on the facts that pain is not usually present at the onset of the disease, and that a skiagram taken soon after the commencement of symptoms shows nothing abnormal. The section on treatment recommends recumbency with traction and immobility throughout the active stage. In the author's practice these are secured by the use of the Pyrford hip frame, a combination of the Jones's abduction and the Carshalton frames, mounted on the Carshalton carriage described in THE LANCET, 1921, i., 1071, by Dr. Gordon Pugh. All cases are fixed in full extension, the widest possible abduction, and negative rotation, on the assumption that if ankylosis occurs it will be fibrous, and that the hip will slowly tend to adduct and flex. An abscess is not interfered with unless threatening to break through the skin or causing pain; the contents are then expressed through an incision which is at once closed. In the author's opinion there is no sure sign as to the exact date when activity ceases; X rays cannot show whether the disease is still active, and clinical experience alone can guide. In the convalescent stage the aim of treatment depends on the degree of destruction. When the cartilage covering the head of the femur is intact, or when it is only in part destroyed and efficient traction has held the femur away from the acetabulum so that the intervening fibrous tissue is of sufficient length to allow movement, the treatment recommended is by patten and crutches or weight-relieving calliper. When the cartilaginous surfaces have been more seriously damaged and the bones allowed to come into apposition through inefficient traction, ankylosis has to be aimed at, the patient being allowed to walk on the affected leg for a year or two in a plaster-of-Paris spica ending above the knee.

The third section of the book, which deals with the results of treatment, is of special interest, differentiating between the end-results that may be expected in disease of the acetabulum, the femoral neck, the synovial membrane, and the head of the femur. Dislocation and subluxation, or wandering acetabulum, are declared to be avoidable and due to faulty treatment; they are serious inasmuch as they always result in an unsound hip and demand further treatment to improve the function of the limb. In the last chapter the question of primary and secondary operations is discussed and a detailed description of the Pyrford frame given.

This little volume is attractive and unusually helpful, and expresses clearly and modestly the opinions the writer has formed after careful study and discriminating observation. It is well printed and illustrated by excellent skiagrams.

### ANATOMY

*Grundriss der Wissenschaftlichen Anatomie* By Dr WILHELM LUBOSCH, Professor der Anatomie in Würzburg Leipzig: Georg Thieme. 1925 Pp 202

WE have gone through this book with great pleasure It is not a text-book of anatomy in the sense usually understood by the student, and it is more than a handbook of morphology applied to the human body It is intended to be a companion volume to the reader's anatomical text-books, to be used with them so that the student may obtain a more comprehensive view of the science which includes within itself the details of the body on which he is working It deals with anatomy in its relation to philosophy, medicine, physiology, and so on, proceeds to consider life and its necessities in organic structure, and thus opens the way to the special morphology of the human subject through general morphology with its many points of view It is possible that the English student would not take kindly to disquisitions on metaphysical matters, but we would like to see such a book in his hands, not because of its new material, nor because the views are always those taught here, but because of the excellent way in which the information is put together The facts are certainly to be found in works in our tongue, but in this work they are placed in proper sequence and the subject is treated as a whole in clear language, and often with commendable brevity Developmental anatomy, moreover, is properly placed in the morphological scheme, although we would have liked to have seen more made of this subject in dealing with the special morphology of the human frame A morphological consideration of the cellular constituents brings to an end a book on which Prof Lubosch is to be congratulated.

### THE SYMPTOMS OF DISEASE

*The Basis of Vital Activity* By Sir JAMES MACKENZIE. London: Faber and Gwyer 1926 Pp 132 6s

THROUGHOUT his pilgrimage from Burnley through London to St. Andrews, Mackenzie was at bottom concerned with one topic—the nature of symptoms As it happened, after some concern with visceral pain, the symptoms of cardiac disease became for many years his preoccupation, and it was the success with which he followed this particular line that brought him to the great position which he deservedly held throughout the medical world. There are many workers who have followed his lead and elaborated his analysis of cardiac symptoms, they have proved beyond doubt that his methods and results in this field are sound and fruitful And in this short statement of his general position, finished very shortly before his death, he sets out to persuade his fellows that similar methods can be applied to symptoms of any kind and that they will yield equally important results if they are pursued sincerely and with patience commensurate with the difficulty of the problem His testament needs close reading and indeed, it must be confessed that his meaning is not always quite clear Symptoms are not, he says the direct result of injuries inflicted on the body; they are produced by the body and are the manifestation of abnormal or unusual activity by some organ or tissue Cells are always either discharging energy or renewing their supply of it; their periods of renewal can be varied considerably and this is the way in which their activities are modified When they are active they exhibit their specific activity and at the same time discharge an impulse which influences other cells and produces the regulation and coördination which is characteristic of the cells of an organ and of the organs of the body Hence permeating all bodily activities is the reflex arc —not, perhaps, a very happy form of words for it gives a wide meaning to an expression which has customarily had a more limited significance The implications of these propositions must be followed in the original and in the experience of the reader, if he concludes that they are ill founded, he will find on the last page that the author admits that that is quite likely But it will do everyone good to reflect as seriously as they can on the definition of a disease as 'the reaction of the body to an injurious agent'

### NOTABLE BRITISH TRIALS

*Trial of Abraham Thornton* Edited by Sir JOHN HALL, Bt. London and Edinburgh Wm Hodge and Co 1926 Pp 183 10s 6d

THE latest volume in the series of Notable British Trials (Rex v Abraham Thornton) lacks the direct medico legal interest of its predecessor, the trial of Ronald True But it has all the human appeal of an unsolved problem and a queer historical interest as well. In 1817, on the morning of Whit-Tuesday, the body of a girl named Mary Ashford was found in a pond near Sutton Coldfield. There was strong suspicion that Thornton had been guilty both of criminal assault and of murder He had been with her at a village dance the previous evening and (as he himself admitted) was alone with her afterwards till 4 A.M, a few hours before her body was recovered from the pond. Footprints corresponding with Thornton's shoes were found hard by, and things looked black for him. He was found guilty of wilful murder by the coroner's jury, but, to the surprise of the countryside, was acquitted at Warwick assizes Then popular feeling running strongly against him, the archaic process of "appeal of murder" (already obsolete for 100 years or more) was invoked against him Under an Act of 1486 the elder brother of the dead girl succeeded in placing him on trial afresh in Westminster Hall. But one archaism was met with another Thornton claimed the primitive right of 'trial by battel' and flung down his gage, which his prosecutor showed no wish to take up Thornton was released a second time, but found his old home too hot for him and ended his life in America This was the last example of an appeal of murder and a challenge of trial by battle for Parliament put an end to these absurd anachronisms in 1819

The main medical interest of the case is the problem whether the modern expert witness would have been able to remove the doubts as to how Mary Ashford met her death A Birmingham surgeon made a post-mortem examination, but his evidence seems strangely brief to-day Sir John Hall, who edits the trial with skill, says there cannot be a shadow of a doubt that Thornton was innocent It would, perhaps, be safer to say that there was at any rate insufficient evidence to the contrary

### CLINICAL DISORDERS OF THE HEART-BEAT

Sixth edition By Sir THOMAS LEWIS M D, F.R.S, D.Sc, F R.C.P, C B.E London Shaw and Sons, Ltd 1925 Pp 191 8s 6d

IN this book Sir Thomas Lewis gives a clear and concise account of the various disturbances of the cardiac mechanism of the manner in which these disturbances can be recognised without instrumental aid, of their prognostic significance, and of their therapeutic indications. As he points out in the preface, it is the duty of investigators to bring to the notice of those who are in a position to apply them the practical results of recent advances in knowledge, freed as far as possible from technicalities The present volume admirably fulfils this object The records used to illustrate the various conditions are confined to sphygmographic and polygraphic tracings The sixth edition follows closely the lines of its predecessor, and the principal innovations it contains are in the department of treatment In 1920, when the fifth edition was published, quinidine was a novelty in cardiac therapeutics Since then it has been extensively employed in auricular fibrillation and in certain other disorders such as flutter, paroxysmal tachycardia, and extra-systoles In the present edition it is included in the therapeutic measures available for the treatment of these conditions. Reference is also made to the massive dose method of digitalis administration in heart failure with auricular fibrillation, and to the use of adrenalin in the Stokes-Adams syndrome. A new diagram is introduced which serves to bring the mechanism of auricular fibrillation more closely into line with that of flutter.

As a straightforward, up-to-date, and thoroughly practical exposition of an important aspect of cardiology this small book well deserves the universal popularity which it has earned with both practitioners and students.

NUTRITION.

*Lexicon der Ernährungskunde.* By Dr. E. MAYERHOFER and Dr. C. PIRQUET. Lief. 3 and 4. Vienna: Julius Springer. 1926. Pp. 337–592. G.M.12.50 and 12.

WE have received the third and fourth instalments of this enterprising work, of which the first two sections received notice in THE LANCET of Sept. 19th, 1925. The scope of the lexicon, as was then indicated, includes all subjects which are in any way connected with nutrition, human or animal. Among the longer articles contained in these two instalments are some of historical interest—e..g, on cannibalism and on the nutrition of primitive races. There are also many which bear directly on present-day questions, such as the relation of sex and nutrition, and army commissariat. The greater part of the work, as before, consists of short articles descriptive of foodstuffs and their raw materials.

## JOURNALS.

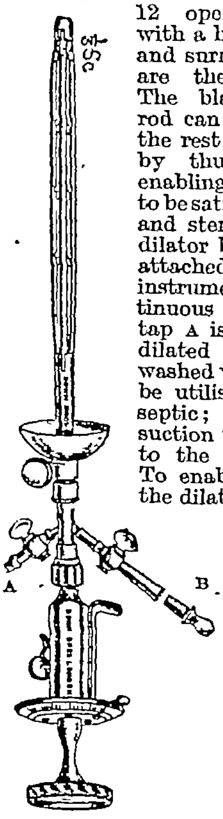
JOURNAL OF THE ROYAL ARMY MEDICAL CORPS, February, 1926.—The laboratory investigation of dysenteries and the identification of the bacillus, if any, concerned depends crucially on the due selection and prompt forwarding of the specimen. These matters have lately been given special attention in India, with the result that, in the Poona district, in the first eight months of 1925, 90 per cent. of the cases examined were found to be bacillary, as against 9 per cent. in the first ten months of 1924, and that most were Flexner-type infections, another great difference, as we are told in a valuable, and at times entertaining, paper by Major J. A. Manifold. As a result, more cases are now treated with serum and salines, fewer with emetine. The urine being passed elsewhere, the stool is collected in a dry, clean bedpan free of antiseptic; a specimen of mucus, as free as possible from fæces, is sent to the laboratory forthwith, the time at which passed and the reaction of the mucus being stated; a film of the mucus and an emulsion thereof in neutral glycerine, 30 per cent. in normal saline, accompany the specimen. If amœbic dysentery is suspected, three fixed films of mucus are sent, and, if cysts are likely to be present, an emulsion in triple strength Gram's solution. All pathologists and others interested in such cases should read this paper for its discussion of laboratory technique, the risk of confusing with *E. histolytica* endothelial cells which have ingested red corpuscles, the inagglutinability of early Flexner cultures and other details, which they will find most helpful. Other excellent articles in this particularly good number are: Venereal Prophylaxis at Singapore, by Lieut.-Colonel P. Hope Falkner; Chloramine Treatment of Water in the Field, more effective than chlorination and without bad taste, by Major C. H. H. Harold; and Large Scale Incineration in the Tropics, by Major A. L. Otway.

TROPICAL DISEASES BULLETIN, February, 1926.—This number contains an especially valuable critical review on yaws and syphilis by H. S. Stannus. In his survey of the literature of the last six years he has included such little-understood conditions as goundou, juxta-articular nodules, and gangosa. The controversy as to the exact relationship of yaws to syphilis, and vice versa, continues to excite attention and is, apparently, still far from solution.—C. M. Wenyon is responsible for résumés of work on kala-azar, relapsing fevers, and other spirochætoses. Rat-bite and yellow fevers are also dealt with by the same reviewer.—A section on malaria by Clayton Lane contains some 50 abstracts, the chief of which is a record of the proceedings of the International Malaria Congress held in Rome in October, 1925.

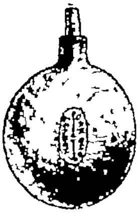
# New Inventions.

## SUCTION DILATOR.

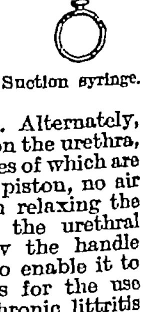
THIS instrument is a modification of Kollmann's dilator to enable suction of the urethral surface to be carried out while the urethra is in a state of dilatation. The central rod of the dilator has 12 openings connecting with a hollow central tube and surrounding this tube are the dilator blades. The blades and central rod can be detached from the rest of the instrument by thumb-screw, thus enabling the instrument to be satisfactorily cleansed and sterilised. When the dilator blades and rod are attached to the whole instrument the central opening is continuous to the side taps A and B. Side tap A is the flushing tap to enable the dilated surface of the urethra to be washed with an antiseptic. The tap B can be utilised as the outflow for the antiseptic; it can, in addition, be used as a suction tap either prior to or subsequent to the washing of the urethral canal. To enable suction to be carried out on the dilated urethra, the dilator is inserted into the urethra with the usual precautions and gradually dilated up. A Bier's bulb, with a valve inserted in the bulb so that on compression of it no air is forced into the urethra, is attached to tap B. Alternate pressure on bulb and relaxation of this pressure exercises the necessary suction and creates a negative pressure on the urethral surface. Alternately, and to obtain greater negative pressure on the urethra, the suction syringe may be used, the valves of which are so arranged that, on pressing home the piston, no air is introduced into the urethra, while on relaxing the piston strong suction is exercised on the urethral surface. By means of a thumb-screw the handle can be detached from the instrument to enable it to be satisfactorily sterilised. Indications for the use of this instrument are subacute and chronic littritis and lacunitis and subacute and chronic infiltration of the submucous tissues. Considerable suction can be exercised on the mucous surface of the dilated urethra without damaging the epithelium. The venous congestion set up by the negative pressure inside the urethra tends to hasten absorption of submucous infiltrates.



Suction dilator.



Bier's bulb.



Suction syringe.

This instrument has been kindly made for me by Down Bros., Ltd., 21 and 23, St. Thomas's-street, London, S.E. 1, and is made of stainless steel.

DAVID LEES, M.B., F.R.C.S. Edin.

LONDON: SATURDAY, APRIL 3, 1926.

## PRINCIPLES OF TREATMENT IN RELATION TO NERVOUS DISEASE.

The Lettsomian lectures, delivered before the Medical Society of London by Dr E Farquhar Buzzard and published in recent issues of The Lancet, deal with an aspect of medical practice of much importance, indeed, his enumeration of therapeutic principles is applicable to quite other departments of medicine than that of neurology Although not stated by the lecturer in so many words, perhaps, one of the most vital of these principles, as far as its possibilities for good or harm are concerned, may be expressed in the form of a question as follows To what extent should the patient be informed of the position of professional knowledge in regard to the curability or otherwise of his disease? Dr Buzzard adopts the view, which some may think even in regard to nervous disease unduly pessimistic, not to say nihilistic, that physicians have no pretensions to curing disease and that they are in a position to act only as Nature's allies and agents. Assuming this attitude, he would thereupon take the patient into his confidence and in well-chosen words outline what is known of the action of various remedial drugs or other medicaments, he would sketch, possibly, the pathology of the particular affection, and would then say that while certain therapeutic procedures, often asked for by the patient himself, are, in fact, useless, some improvement might be possible by certain other methods, though the morbid process itself is still without any proved, specific, antidote The Parkinsonian would be told to place little or no reliance on treatment, the neurosyphilitic would be informed that treatment is to go on for the rest of his life, the patient with progressive muscular atrophy or bulbar palsy would learn that the cause of his affection is unknown and that no trustworthy remedy exists.

These, it will be seen, are merely examples of how the general principle works in particular cases, and it is clear the adoption of such an attitude on the part of the physician requires a degree of moral courage as well as a due modicum of personal tact and sympathetic insight We think the experience of all who are in a position to express an opinion that carries weight will be in favour of the plea that the patient should be taken into the physician's confidence, provided the former is of sufficient intelligence to appreciate the facts, and of sufficient level headedness to discount beforehand any depression of spirits such information may entail. On the presence of these two features in the "make up" of the individual concerned much obviously will depend Over and over again in clinical medicine is the doctor called on to decide whether absolute honesty is the best policy, and whether, as Dr Buzzard says with truth, he will run the risk of losing some patients while he endeavours to save them the misery of those alternating hopes and disappointments which are the lot of the incurable seeking cures The problem is age-old, and probably no hard and fast solution of universal applicability is practicable Some patients do not want to know medical details about themselves, and do not wish for blunt acquaintance with prognostic and therapeutic facts, where ignorance is bliss, they may quote with approval, *'tis folly to be wise* Others, again, may be judged not to be composed of such stuff as will resist the blow which full revelation of the nature of their nervous malady will strike them Still others will listen unmoved to sentence of ultimate death, as it may amount to, and yet not accept the decision as final They will not entertain the idea of incurability, even though the physician qualify his pronouncement with some emendation such as "in the present state of our knowledge", they will catch at any straw floating on the stream bearing them away, and who is to say human nature errs in this respect? What constitutes incurability? And how are we to know that this or that novelty in neurological therapeutics is valueless unless it is given a long and fair trial? Indeed, it is a sort of stock argument with those who resort to unqualified practitioners and for whom Dr Buzzard has a scathing comment that not a few of our recognised therapeutic methods owe their inception to the empirical discoveries of individuals outside the ranks of the orthodox profession. While we must be prepared to ignore the misapplication of this argument it is well, we think, not to be too dogmatic in respect of incurability, or too modest in regard to what we may be able to accomplish. After all, each case should be decided on its intrinsic merits, while we can legitimately inform the Parkinsonian that hitherto no specific treatment has been unearthed, or the bulbar paralytic that the specific remedy is the discovery of the *elixir vitæ*, we need not confess to entire therapeutic helplessness. With the right kind of patient, intelligent enough to realise his own and his physician's limitations, it is a pleasure often to coöperate in the endeavour to try out, it may be empirically, some remedial measure, some novel therapeutic technique, which at least furnishes him with the mental satisfaction that something is being done Such efforts call to deep seated instincts within the sufferer's breast and are not wisely relinquished. For not a few nervous affections our attempts at treatment would be more scientific were we not too often wedded to conceptions of them gleaned solely from consideration of their morphological pathology. Examination of the morbid material obtained from a case of anterior poliomyelitis or of disseminated sclerosis provides us with little information in regard to the processes at work, and still less in respect of the postulated virus. Not until experimental pathology took charge of research concerning the former of these was any real advance made in the direction of rational treatment, and the same lesson will have to be learned in connexion with the latter Dr Buzzard extols, rightly, as most will agree, the usefulness of arsenic and arsenical compounds for cases of disseminated sclerosis, yet their employment is not based on a rational or scientific therapeusis, since the cause of the disease remains undiscovered, however near we may be to that desirable eventuality. Similarly, with the use of bromide in epilepsy—its clinical value is justly stressed by the lecturer, even if the intimate nature of the affection is as elusive as ever, and its origination as indefinite as in the days when epileptics were judged to be possessed As far as these and other neurological ailments are concerned, incurability must be a relative and not an absolute term, at any moment the phase of uncertain knowledge may be succeeded by that of certain knowledge, and the disease from pathogenic obscurity into the full lig from ætiological solution

It is interesting and noteworthy that should assign prominence to psychoth it to be still the most valuable weapon we possess for every-day use in our array of remedial agents. He uses the term in its widest sense, and regards it as an essential factor in the treatment of all patients suffering from organic disease. Doubtless few will be found to quibble with this contention, since all clinicians who impress their personality on their patients, winning their confidence and trust, and paving the way for coöperation, are, as a fact, exercising psychotherapeutic principles whether they realise it or not. Generations of physicians have done the same before us. But the neurologist is more concerned with the technical usefulness and usableness of strict psychotherapeutic procedures in the handling of the classes of patient he meets in practice. According to Dr. Buzzard the only psychotherapy permissible for the manic-depressive psychotic is "sympathetic encouragement and the daily audience of his woes"; the anxiety neurotic, on the other hand, requires mental probing and investigation, as does the psychasthenic, who suffers from phobias and compulsions. The hysterical patient, too, is a fit subject for the art, which is stated to include suggestion, education, and investigation methods. It would be informative to have in some critical shape the embodied experience of neurologists as regards the results obtained by recourse to these procedures; data bearing on recovery, relapses, and recurrences, on amenability to treatment of different clinical types, on the influence of the methods on constitutional as opposed to symptomatic phenomena, would prove of service. If psychotherapy is as indispensable as it is claimed to be, the clinician should not only familiarise himself with its technique, but should be instructed in the art of selecting methods for cases; psychotherapeutic knowledge should be much more systematised than it is at present, more standardised, more accessible. But our psychotherapists disagree among themselves; hypnotic measures are effectual in the hands of some and permanently tabooed by others; psycho-analysis is a therapeutic sanspareil according to one school, and distinctly over-rated according to another; Couéism, so to describe it, answers all the calls that are made on it, according to a third. The physician who would be true to himself and who fights shy of any treatment even remotely suggesting charlatanry or humbug is sometimes hard put to it to deal effectually with the minor psychoneurotic disorders that abound in these days; his position would be strengthened were he able to refer to a consensus of medical opinion as to the relative usefulness of different forms of treatment. The profession will not be lifted above rivalry with quacks, as Dr. Buzzard urges, unless therapeutics are based on sound knowledge derived from anatomical, physiological, and psychological considerations; however arduous the road to follow, and it becomes more laborious with every increase in medical lore, we cannot imagine the profession as a whole even hesitating to face it.

## THE INTOXICATED MOTOR DRIVER.

In Monograph No. 1, issued by the True Temperance Scientific Committee, and entitled the Problem of the Intoxicated Motor Driver, there is much that is true, temperately stated, and scientifically interesting. The law is not perfect, though Section 40 of the Criminal Justice Act of 1925 (which comes into force next June) modernises it by definitely penalising "any person who is drunk while in charge on any highway or other public place of any mechanically propelled vehicle." It is not certain, however, that the Committee will cure the law's imperfection by its recommendation that the words "drunk" and "drunkenness" shall be expunged from the statute book, and that emphasis be laid rather "on the incapability, disorderliness, nuisance, or danger resulting from the alcoholic intoxication." To eliminate "drunkenness" and to let the word "intoxication" stand will leave the old problem unsolved. The Committee's argument is that the law objects not so much to drunkenness in itself as to drunkenness in relation to environment or occupation; the legal offence is not being drunk, but being drunk and disorderly, drunk and incapable, drunk in charge of a child, or in possession of fire-arms, and so on. But this is not the whole story. Simple drunkenness, unaccompanied by other conduct on the part of the drunken person, does exist upon the statute book; the offence may consist partly of conduct on the part of some other person who may be perfectly sober. There is the offence of permitting drunkenness on licensed premises, procuring a drunk man a drink, selling him fire-arms, or taking a pawnbroker's pledge from him. The law, of course, is more concerned with what a man does than with what he is (the Post Office Act even uses the words "guilty of an act of drunkenness"); it is easier to prove what he does than what he is. But in the end we come back to the necessity for some simple word like "drunk" which all can understand. "His gait was unsteady," says the police witness, "his breath smelt of alcohol, his face was flushed, his pupils were dilated ——" "Yes, yes," interrupts the magistrate, who is willing to leave these symptoms to cross-examination, "what we want to know is, was he drunk?"

The Committee goes on to recommend that, until the law gets rid of the word "drunk," magistrates should be allowed to interpret "drunkenness" in different degrees according to the circumstances. "Thus," says the monograph, "a motorist would be defined as drunk at a considerably lower degree of intoxication than would be required for a pedestrian and at a slightly lower degree than for the driver of a horse-drawn vehicle." Degrees of drunkenness and of danger are already taken into account at present in assessing penalties; if the Committee means that a magistrate is to convict as "drunk" a motorist who is not quite drunk, fresh legislation will be required. Finally, the Committee refers hopefully to the urine test for alcoholic concentration. Dr. Godfrey Carter's paper on this subject, read to the Medico-Legal Society last January, was reported and discussed in The Lancet[1] at the time. Dr. H. W. Southgate, who (as our report showed) then explained the tests on alcohol concentration in blood and urine which he had been conducting for four years, is one of the True Temperance Scientific Committee whose names appear on the monograph under the presidency of Sir James Crichton-Browne. The Committee observes: "The urine test for alcoholic concentration, if clearly proved to be reliable, should be adopted as a routine test, a portion of the urine being always reserved for the examination if desired by the individual's private doctor and by some responsible analyst as well." This is an admirable proposal, subject to obvious qualifications. In the first place, persons who have just been taken into custody will not necessarily submit to tests which are voluntarily undergone in the course of medical examination on other occasions, nor are the courts likely to accept refusal as indication of guilt. A more important reservation is already indicated by the Committee's words "if clearly proved to be reliable." Proof will be clear only when it is no longer possible for a defendant to produce medical evidence that the urine test for alcoholic concentration is unreliable. This is by no means yet the case, but the investigation is at any rate promising, and the Committee does well to draw attention to it. There is plenty of room for philosophic and scientific inquiry into the questions "What is drunkenness?" and "What is true temperance?" and there is certainly no occasion when the diagnosis of drunkenness requires more anxious consideration than where the action of a motor driver is concerned.

# INTERNATIONAL HEALTH ORGANISATION.

INFORMATION as to public health progress each year in various countries has not hitherto been available in a form convenient for comparison. Handbooks setting out the conditions under which the national health is officially and unofficially promoted in certain countries were published in 1924 and 1925 under the auspices of the League of Nations,[1] but though a detailed questionnaire had been circularised there was little uniformity in the sequence or even the substance of the data supplied. Moreover, the development of public health activity is rapid, especially in those countries whose method of government has been reconstructed since the war. Recognising that changes in legislation and procedure are constantly taking place, the Health Section of the League of Nations have arranged to supplement the information offered in the handbooks, each of which was prepared by a member of the health administration concerned, by the issue of an annual progress report, in which the more important developments of the preceding 12 months in each country are reviewed. In the first of these reports, which bears the title International Health Year Book, 1924, it may be said that the current activities of 22 countries are described, for legislation passed or statistics recorded any time up to the first part of 1925 are included. In these summaries, which vary in length from the brief eight pages emanating from Canada to the 42 pages supplied by Spain, an effort has obviously been made to collect information as far as possible under corresponding headings for each country. Not all the authors have fallen in with the scheme, but most of the reports are divided into four or five sections. In the first of these, area, population, birth- and death-rates, infantile mortality, and budgets are set out. The second describes recent reforms in health administration and legislation. The third is devoted to preventive medicine and hygiene, under the subheadings tuberculosis, cancer, venereal diseases, malaria, trachoma, alcoholism, maternity and child welfare, and mental hygiene. The fourth section, entitled curative medicine, discusses hospitals, sickness insurance, numbers of doctors, students, and midwives, and medical education. A fifth more general section is mostly devoted to the control of foodstuffs, drugs, and biological products, while notes on housing and methods of health propaganda also find a place. Even where this orderly arrangement has not been followed, an admirably compiled index enables students of a particular subject to pick out the relevant section in each of the 22 articles without effort. Those who wish to compare each nation's methods of combating tuberculosis, venereal diseases, or diphtheria will see at a glance where to find them without having to read about drainage systems, hospitals, or budgets. Incidentally, the figures given under the last-named heading are the least profitable, since without a table of the relative values of the national currencies and an estimate of the cost of living no useful comparisons can be made. Those countries which do make a statement on the cost of living—Bulgaria and Latvia—have to record a continuous rise. In Bulgaria the index, calculated as 100 for the years 1901 to 1910, had risen to 2192 in 1920, since then increasing every year to 3703 in 1924. The State has since attempted, by offering the communes credit for food-supplies, by an alteration in its export policy, and by the establishment of cheap railway tariffs, to check any further advance.

The relapse into less civilised conditions which has been the fate of many of the belligerent European countries is manifest, but their painful struggles to recover from the degradation caused by severe economic distress are no less evident. In Bulgaria an epidemic of typhoid fever in 1924 (7127 cases against 2790 in 1923) is attributed to lack of drainage, of sanitary conveniences in houses, and of a supply of pure drinking water. The prevalence of trachoma in Slovakia is said to assume the character of a social scourge affecting 50,000 out of the 3 million inhabitants. Energetic measures to combat the disease, including free dispensaries under expert medical and nursing supervision, were initiated in 1924; in that year 118 communes with 60,000 inhabitants were examined and some 5000 trachoma patients discovered and treated. An unusually comprehensive system of sickness insurance has been instituted in Esthonia. This includes treatment in hospital when required, with full maintenance and assistance in confinements. From Germany comes the welcome news that the mortality from tuberculosis was considerably lowered in 1924, but the incidence of the disease has apparently increased. In the section on medical education the numbers of medical students at German Universities is given for the years 1921 to 1924. The men students decreased in number steadily from 18,933 to 7728 during this period; the women also decreased, but only from 1937 to 1328. Greece reports a satisfactory situation with respect to epidemics. During the last 12 years of all the Balkan countries Greece has had the fewest victims from cholera, small-pox, and typhus. Moreover, in 1924 those diseases which were epidemic in 1923 have been checked—for example, encephalitis lethargica claimed only 13 victims, with 3 deaths, against 694 with 84 deaths. In Latvia, as a legacy of the old Russian administration, there remain some 160 registered "assistant doctors" who are allowed to practise within certain limits; it is stated that this profession will cease to exist in 10–20 years. The campaign against venereal disease in Austria is complicated by the increase in unregistered prostitutes, but is being actively pursued. In this country a law passed in 1924 defines the regulations for the practice of midwifery and provides for compulsory revision courses for midwives.

In contrast to the struggle of the war-spent countries to reorganise their health services is the steady progress made by some of the neutral countries and by the United States of America in their efforts to consolidate, improve, and extend systems which have had no rude set-backs. Administrative changes adopted during the period under review in these countries are concerned mainly with the further development of a public health organisation of proved value, or with State control of activities started by voluntary enterprise. In 1924 official recognition by the Spanish Department of Public Health was given to the anti-malarial organisation set up during the previous four years. An extensive campaign has now been undertaken under the direction of a central committee. A six months' course has been organised for ten doctors chosen from among the applicants; three months are spent in laboratory work followed by three months' training under supervision in a malarial district. This course was started in April, 1925. In the United States many important health matters are not under the jurisdiction of the Federal Government, but are controlled by the several States. The section on recent developments in health administration and legislation records for the most part laws which have only local significance. For example, in six of the States but not in the rest, a man must produce a certificate of freedom from venereal disease before receiving a marriage licence. Other even more curious anomalies are manifest if this section is carefully studied. It may be that the method of trial on a small scale is likely to lead to good results, especially if legislative assemblies profit from the experience of neighbouring States. Similarly a study of the International Health Year Book, supplemented by the exchange of visits between European public health officials organised from time to time by the League of Nations, should enable the older countries to learn from each other and to discover the most effective ways of coping with existing causes of ill-health and preventing the introduction of fresh ones.

"Ne quid nimis."

## THE NEW OPIUM POLICY OF THE INDIAN GOVERNMENT.

IN opening the Council of State last February the Viceroy of India announced a new policy of the Indian Government in the matter of the opium trade which is as welcome as it is revolutionary. This policy the Viceroy declared to be "in accordance with the trend of modern opinion in a number of other countries and also with views which have been freely expressed in some quarters on different occasions in India." Only four years ago the India Office, in an official statement entitled "The Truth about Indian Opium," maintained that the Government of India stood unhesitatingly on the findings of the Royal Commission of 1893–95. That report justified the Government opium monopoly, the Indo-Chinese trade, the export of Indian opium to the Far East, and demurred to the loss of revenue which the surrender of such trade would involve. It is true that Lord Morley, when Secretary of State for India, admitted that the report of that Commission had failed to carry conviction, yet even at the Geneva conferences in 1924–25 the British delegates expressed themselves as quite satisfied with the present system of production and distribution of opium by the Indian Government and maintained, "Everything is controlled by the Government, and effectively controlled." The Indian Government's representative at Geneva described his Government's policy as that "of deriving the maximum of revenue from the minimum of consumption." There has undoubtedly arisen a strong movement in India itself against the Government policy both in the matter of purveying opium for eating to the natives and of exporting large quantities of the drug well knowing it is to be used for smoking purposes. A booklet recently published by the Student Christian movement from the pen of Mr. C. F. Andrews, entitled "The Opium Evil in India," has drawn attention to the evils arising from addiction to the drug especially in the cities, while the report of the "Assam Congress Opium Enquiry" gives evidence of the prevalence of abuse of the drug in that province both by eating and smoking and of the need to limit its production to what is necessary to meet legitimate medical requirements.

The new policy, now announced, while throwing over the official apologists for past action, is intended "to reduce progressively the export of opium to all destinations so as to extinguish the trade altogether within a definite period except for strictly medical purposes." It is recognised that "this policy will involve a corresponding reduction in the amount of opium produced": if it is also held to involve the reduction of the supply of Government opium for internal consumption to that required "for strictly medical purposes," it will have achieved the objects at which the International Opium Convention of 1912 was presumed to have aimed.

## THE BIRMINGHAM MEDICAL INSTITUTE.

THE *Birmingham Medical Review* first appeared in 1872 as a quarterly journal. After a while it became a monthly, and it only ceased publication with its 470th number owing to the difficulties of the war. N[illegible] g a welcome return in a new series, of which the first copy[1] appeared in January, incorporating the *Midland Medical Journal* as well. It is the official journal of the Birmingham Medical Institute, which entered its new premises in Great Charles-street in 1924, and, under the presidency of Colonel Frank Marsh, has become more and more firmly established as the centre of medical life in the city. The Institute has a valuable library of 16,000 books to which additions are continually being made; there is a comfortable reading-room with a large number of current periodicals, and light refreshments can be obtained in a tea-room. It is used for the meetings of the local branch of the British Medical Association, the Midland Medical Society, the Midland Obstetrical and Gynæcological Society, and the Birmingham and District Medical Women's Association. The Panel Committee is also housed there. The Midland Medical Society is now a section of the Institute, and it is to be hoped that much good will come of these coördinated arrangements. The *Review* itself is an excellent production. It is edited by Dr. K. D. Wilkinson, who has the assistance of a representative editorial committee, with Prof. W. H. Wynn as chairman, and it deserves a large circulation. The first number contains the first Ingleby Lecture for 1925, delivered at the University of Birmingham by Dr. J. G. Emanuel on Auricular Fibrillation, and an entertaining address by Dr. A. V. Bernays mainly on the text "Knowledge comes, but wisdom lingers." There is also an article on the Treatment of Acute Perforative Peritonitis by Mr. G. P. Mills, and a memoir of Dr. William Withering by Prof. Wynn. The journal should do much to encourage medical men to join the Institute, the membership of which at present stands at only 262. It is hoped to arrange for a composite subscription to include use of the buildings, membership of the Midland Medical Society, and the receipt of the *Review*.

## MECHANICALLY-COOLED REFRIGERATORS.

ONE of the most interesting features of the *Daily Mail* Ideal Home Exhibition at Olympia was the display of electric refrigerators. Several firms showed a considerable range of these appliances, all designed for running from ordinary house lighting circuits. The principle of most of the refrigerators is the same and depends on the rapid absorption of heat from the surrounding medium occasioned by the boiling of sulphur dioxide under reduced pressure. The gas system is a closed circuit of metal tubing connected with a cylinder of liquefied sulphur dioxide. This part of the apparatus is charged before the refrigerator is installed and needs no attention, as the gas is re-condensed automatically and used over and over again. The reduction of pressure and circulation of the gas is maintained by a small suction cylinder operated by an electric motor, the whole apparatus being neatly arranged in the base of the refrigerating cabinet. Both British and American models are to be had, the former being run by a quarter horse-power water-cooled engine, the latter by a half horse-power air-cooled type. The cold water system of the British model, shown at the "Freezone" stand, is claimed to reduce the cost of running, and enable the machine to work at very low pressures. The air-cooled models are slightly less trouble to fit up as it is only necessary to have a wall-plug and switch to complete the connexion. The "Electrolux" unit differs from the "Frigidaire" and from most of the others in that its efficiency depends not on sulphur dioxide but on the evaporation of ammonia inside a hermetically sealed apparatus. No compressor with valve and therefore no motor is required, but only a small quantity of heat—which may be supplied by electricity, gas, or oil—to start the evaporation and control the circulation of the refrigerant. Various sizes and shapes of cabinet are obtainable ranging from small household models to large cold-storage cabinets capable of holding carcasses of meat.

---

[1] Birmingham Medical Review. Birmingham: Cornish Bros., Ltd. 1s. 6d.

All the outfits appear to be provided with some form of thermostatic cut-out, thus obviating loss of power and maintaining any required temperature from five degrees below zero upwards to room temperature. Fluctuations of temperature are guarded against by the presence, usually about the centre of the cabinet, of a large cold coil surrounding an ice-making contrivance. The ice is made by filling the special containers with tap-water, replacing them in the cabinet, and turning on the switch. The time required to produce ice depends on the setting of the thermostat and can be varied from two to six hours at pleasure. The cabinets are for the most part lined with white porcelain, all the angles being rounded to facilitate cleaning. The "Barnet" refrigerator, a Canadian production, is not mechanically cooled but is essentially an ice chest de luxe. It is very well insulated and has a ventilating system which prevents the possibility of stagnation of the air in the refrigerator when the doors are closed. In this cabinet, such varied articles as kippers, Gorgonzola cheese, onions, coffee, and tobacco can be stored side by side for 72 hours without contaminating each other with their respective flavours. Under ordinary running conditions the inside temperature is maintained slightly below zero, so that the inside of the cabinet remains quite dry, an advantage over the usual form of ice-box.

Though appliances of this kind are widely used in American hospitals, in this country it is the commercial world rather than the scientific which has been the first to take up electric refrigeration—a fact which may be accounted for by the high price of the outfit. Compared with the initial outlay the running cost appears to be low, most refrigerators consuming from two to six electrical units in 24 hours. Once installed, the apparatus needs hardly any attention beyond an occasional drop of oil for the motor bearings, and the running is practically silent. The possibilities of electric refrigeration in hospitals and laboratories seem to have been somewhat overlooked up to the present, yet the possession of a low temperature thermostat working from the ordinary lighting circuit would be a great boon to many departments. Whether they are yet likely to replace ice-boxes for domestic use depends on the extent to which the initial cost can be reduced. A plea for the more extensive use in households of cold as a preservative of food is the substance of an interesting little volume just published entitled "Food Wisdom."[1] It contains illustrations and descriptions of various forms of ice-boxes and mechanically-cooled refrigerators. A paragraph purporting to estimate the comparative initial and the running cost of the different types of refrigerators in the home, begs the question since the price of the units is not mentioned. It is stated that the running cost of a good mechanically-cooled model should not exceed 2*d.* or 3*d.* a day, whereas the cost of replenishing an ice model is likely to be 5*d.* or 6*d.* daily, reckoning the cost of ice at ½*d.* per pound. These estimates admittedly depend on at least two variables, the retail price of ice in small quantities and the rate charged for electric current; and to deduce from them that for middle-class households the heavier initial cost of the mechanically-cooled apparatus will "soon be more than made up and there will be an actual saving" appears to us unjustifiable at present, though the statement may have prophetic significance. The present retail prices of the smallest model on the market of the mechanically-cooled refrigerator named above are "Frigidaire," £61; "Electrolux," £30 10*s.*; and "Freezone." The middle-class housewife in this temperate climate will hardly be tempted even by low-running costs to embark on such a purchase, for the days on which ice is anything but a luxury are few. However, the arguments set out by Mrs. Cottington Taylor in favour of using cold as a food preservative are unanswerable, and we trust that manufacturers will soon be able to give middle-class housewives an opportunity of profiting fully from her advice.

## DEEP DIVING.

THE *Laurentic* was a 15,000 ton Atlantic liner which was taken over by the Admiralty during the war and converted into an armed cruiser. Early in 1917 she sailed from Liverpool with five million pounds worth of gold bars for Halifax, and was sunk by mines off the Donegal coast in 120 feet of water. Diving operations were soon begun, the strong room reached, and a little of the gold brought up. A violent gale then interrupted operations, and when the divers were able to get down again they found that the ship had broken up and collapsed, and that the gold was buried at the bottom of the ruins. So they set to work to break and blast their way through the remains, and when operations finally ceased in 1924 more than 98 per cent. of the bullion had been retrieved, and that without loss of life or any serious injury. The bracing narrative of this triumph of applied physiology is told in the *Journal of Hygiene* (1926, xxv., 26) in a most interesting way by Captain G. C. C. Damant, R.N. (retd.), who was throughout in charge of the operations and who will be remembered as having collaborated with Prof. J. S. Haldane in working out experimentally the theory of compressed-air illness which found expression in the Admiralty rules for diving of 1907. These rules, based on the rates at which the body becomes saturated with nitrogen in compressed air, and at which it gets rid of the excess on returning to atmospheric pressure, were used in diving at the *Laurentic*, and, with one exception, proved very satisfactory; if anything, indeed, they erred on the side of safety. Experience showed, however, that a longer time ought to be allowed between two dives than the regulations suggest; getting rid of the last of the excess nitrogen absorbed under pressure takes longer than had been supposed, and Captain Damant found that lengthening the interval from one and a half to four hours was not really enough to make the second dive as safe as the first. In all, out of about 5000 dives at a pressure of about 55 lb. per square inch, there were 31 cases of illness. One was blind, one paraplegic, and two or three others had nervous symptoms; the pains in and about the joints, known as "bends," were the most frequent trouble. An adequate recompression chamber was provided on board the diving ship from the beginning. This, as Captain Damant points out, gave everyone confidence and proved quite efficient in curing the cases of illness. Violent muscular work during the ascent from the bottom seemed to help to prevent symptoms, and breathing oxygen after reaching the surface also appeared to be of value. Everyone will congratulate Captain Damant on a happy issue to a difficult and dangerous piece of applied physiology.

## AFTER-EFFECTS OF ENCEPHALITIS LETHARGICA.

SCHOOL medical officers have special opportunities of studying the results of encephalitis lethargica. Long after the acute stage is over serious alterations in the nervous system may appear and persist, increase, or slowly diminish through a period of several years. Information is needed as to the course and prognosis in these cases and the best way of dealing with them. Many parents will not keep these children under prolonged treatment and observation, so that practitioners and hospital staffs lack the opportunity to follow them up. But in the schools these after-effects and the conditions influencing them may be observed over long periods and in comparatively large numbers. In large towns, such as London, Liverpool, Manchester, and Bristol, data have been collected in the school reports, and in Sheffield the local medical research committee is studying the disease with the coöperation of the school medical officer. The main after-effects fall into four groups: (1) Parkinsonian syndrome; (2) other disturbances of motor nervous system, such as ocular paralysis and spasmodic movements; (3) mental impairment affecting mainly intellect; and (4) mental changes affecting emotion and volition. Some of the facts which school experience has elicited about these after-effects may be set out categorically thus:—

---

[1] By D. D. Cottington Taylor, A.R.S.I. Assisted by P. L. Garbutt, A.I.C. London: Sir Isaac Pitman. 1926. Pp. 136. 2*s.* 6*d.*

(a) After-effects tend, on the whole, to be more severe and permanent when the illness has occurred in early life. (b) Various classes of sequelæ may occur almost independently or are at least not positively correlated—e.g., the cases showing the severest paralysis are often not those with the most mental changes. (c) Cases showing the most temperamental instability are sometimes the children of neurotic parents, and inquiry frequently reveals that the child showed definite signs of an unstable nervous system long before the illness. (d) Symptoms such as disturbance of sleep rhythm and ocular signs are found early and often diminish later, while changes in the nervous system and mentality manifest themselves much later. (e) Intellectual impairment, when it occurs, is not commonly severe enough to render a child suitable for education in a special school for mental defectives. (f) Prognosis is still uncertain, a fair proportion making more or less complete recovery, but those with definite signs of paralysis usually do badly. (g) Exclusion from school, especially in cases without paralysis, with consequent running the streets, usually is apt to make matters worse. (h) Many cases may profitably return to school after a few months' convalescence, the occupation and discipline being beneficial. (i) Many others can benefit from education and training, but need conditions somewhat different from those at an ordinary elementary school. (j) In a few cases where delinquency has brought them within the law, the firm discipline and care of an industrial school has had a good influence on the character, though there are others who have entirely failed to respond. (k) There are a few cases with marked intellectual failure which must be treated as mentally defectives, but the great majority are not suited for such treatment.

The consensus of opinion is at present in favour of dealing with these children as a separate group, certifying them, if necessary, as physically defective, and sending them to special classes attached to a school for the physically defective or to an institution such as that recently opened by the Metropolitan Asylums Board at Winchmore Hill. Either method should afford valuable experience for future guidance.

## ACCIDENT PREVENTION AND SCHOOL-CHILDREN.

The Third International Congress for Life-saving and First-aid to the Injured is to be held at Amsterdam next September, and we reported last week (p. 683) the meeting of the British Council which is helping forward the arrangements. The whole subject is now being studied from a wider standpoint. The statistician has been shepherding into the epidemiological fold occurrences usually designated "accidents"; at the same time modern views on their occurrence and their prevention have been undergoing great modification. The personal factor, entitled "carelessness," is now recognised to be far more responsible than obvious risk, such as unguarded machinery. This factor is being found to depend partially upon ignorance of risk and partially upon a definite predisposition to sustain accidents which are associated with ill-being or a predisposition to sickness. These views are only slowly being adopted in this country, but in America[1] they are being widely accepted, and are receiving practical application in many directions. Perhaps no extension is more interesting than a widespread scheme of safety education in the schools as an introduction to the prevention of accidents in industry and in later life generally; it is accepted by employers as a logical method of preparing for safety work in the factory and the mine. Accidents are divided into groups—e.g., street accidents, fire, falls, and so forth—one for each month of the school year. Safety committees are formed among children; scouts are set to guard street crossings coming to and leaving school; newspaper reports of accidents are discussed and essays are written. The spirit is introduced in class work; thus arithmetic is done on accidents figures, which are also used for making graphs, while for drawing safety-first posters may be used. Outside school hours fire-drill and games give other opportunities. The scheme does not discourage facing the element of danger, but teaches the right and most efficient way; it does not encourage cowardice, but instructs the brave. Just, however, as health is necessary to receptivity in all education, so here "an awkward, cautious child is more apt to get hurt than the child who apparently takes chances, but whose senses are keen and body responsive and under perfect control." Already 276 towns are reported to have introduced some form of safety teaching in the schools and results are becoming apparent. Motor-car accidents increased steadily at all ages from 1911 to 1919, but the next two years showed a decrease, mainly concentrated in the ages 5 to 15; in Portland, Oregon, accidents to school-children fell from 160 in 1920–21 to 60 in 1921–22; in Detroit the number of children killed fell from 96 to 30 in the year following the introduction of safety work. Will school medical officers please copy.

## RICKETY DEFORMITIES.

Recent discussions in Paris have revealed so much difference of opinion on the treatment of rickety deformities that the *Vie Médicale* (Feb. 26th) has held a kind of symposium on the subject. The impression gained from a study of all the contributions in it is that in France, and also perhaps in Switzerland and Italy, expectation of the spontaneous correction of these deformities is much stronger than in this country. Prof. Camera goes so far as to say that during the three years that he has been at the head of the children's surgical department at Turin he has not seen one case needing surgical intervention. Patients are nowadays brought for treatment at a very early stage, and it is gratifying to compare the present state of affairs with that of 20 or 30 years ago. In the 11 years 1895–1905 719 cases in Turin required surgical intervention. Among the French thalassotherapeutists—under which name are grouped those who believe in the specific virtues of sea air—some stoutly maintain that all, or nearly all, rickety curvatures disappear spontaneously at the seaside, while others admit that only in slight deformities can spontaneous cure be expected. The surgeons hold similar views, but less emphatically. They ask whether it is reasonable to leave the deformity alone for from two to five years at the expense of loss of stature and of probable static troubles. In this country it is a surgical commonplace that marked rickety curvatures are very seldom seen in the adult. What has become of the badly deformed rickety children of the end of the last century who were not operated on? There is no ground for assuming an excessive mortality among them, and it is necessary therefore to accept the hypothesis of spontaneous correction, despite the probable presence at one stage of extreme eburnation. Probably most British surgeons, in the national spirit of compromise, would decline to accept hard-and-fast rules. They would consider it bad treatment to keep a child off its feet for years, under all the developmental drawbacks thereby entailed, when in slight cases by the use of splints and in severe ones by osteoclasis or osteotomy the period of recumbency can be either avoided or enormously shortened—to the great gain of the child's physical and mental development.

## THE HEALING OF GASTRIC ULCERS.

The most striking difference between gastric ulcers produced experimentally and those encountered in human subjects is, perhaps, that the former are a type of ulcer in which it is extremely difficult to prevent healing from occurring, whilst in the latter chronicity is a prominent feature. So much is this the case that it has occasionally been alleged by responsible surgeons that chronic gastric ulcers in human subjects never heal, and that therefore gastrectomy is the sole logical treatment to be advised. Such extreme views can scarcely be supported, but it is certainly true that conclusive evidence of the healing of gastric ulcers in human subjects is difficult to produce. The observations of Nielson[1] point to definite healing in a considerable number of cases traced during 22 years, though the proportion of permanent cures was low in the more chronic group of ulcers. Recently, X ray observation of cases during and subsequent to medical treatment has tended to show the disappearance of ulcer craters, but such evidence requires much repetition and skilful application in order to be convincing. Peculiar interest, therefore, attaches to a recent paper[2] by Crohn, Weiskopf, and Aschner of the Mount Sinai Hospital, New York. In a number of cases of peptic ulcer these observers have been able to demonstrate the disappearance after treatment of the ulcer niche seen with X rays. But in addition to this they produce final evidence not only from subsequent laparotomies, where the healed ulcer has been visible and palpable to the surgeon, but also in several cases where partial gastrectomy has allowed microscopic examination to be carried out of sections through the scars of the healed ulcers. A very long history or a previous dangerous hæmatemesis had justified operative treatment in these cases, and the histological sections showed the process of healing to have consisted of obliteration of the crater by the growth of firm granulation tissue from the sides and base of the ulcer, the lateral surfaces becoming approximated and healing finally accomplished by the ingrowth of epithelial tissue from the sides of the wound. Whether such healing is permanent is, of course, not certain, being decided probably by circumstances which vary in different cases. It is of interest to note that in this series of observations the writers have come across several examples of the so-called "hæmatemesis without lesion," in which no evidence of ulcer was obtainable, but in which a chronic ulcer became demonstrable in later years.

## THE HISTORY OF COLLOIDAL CHEMISTRY.

THE summary of the historical aspect of colloidal chemistry, to be found in nearly all of the many books recently published on this subject, tend usually to follow the same pattern. There is a fleeting reference to Faraday, and a detailed account of the researches of Thomas Graham, universally hailed as the father of colloids. Next we are led to consider Brown's observations on the phenomenon first described by him, and later we advance to the present-day views via Zigmondy and his co-workers. Practically every book in every language commences thus. Those prepared for a familiar repetition in the French language of this well-known story will be gratified on opening a book by Prof. W. Kopaczewski[3] to find facing the title page the photograph of one Francesco Selmi, whose name is probably unknown to them. They will be still more interested to find from the first chapter that the history of colloids dates from the writings of Bernard de Palissy in 1561. According to Prof. Kopaczewski colloidal sols of gold were prepared by the alchemists in the Middle Ages for drinking purposes. He describes research by quite a number of alchemists and chemists in 1674, 1701, 1707, and 1801. He then introduces us to the researches of Francesco Selmi, who in 1830 to 1854 distinguished between colloidal and true solutions. Graham came on many years later, and, according to the author, merely added the name "colloids," and applied the methods of diffusion. Prof. Kopaczewski sums up his view by stating, "Selmi est incontestablement le créateur de la science des colloides." This does not end the shocks to our classical views as to the history of colloids. Brownian movement was not apparently first seen by Robert Brown in 1827, but had been observed by Buffon and by Spallanzani years before. The historical summary lays great stress on the work of Marian Smoluchowski upon the mathematical side of the question. The fact that the rest of the book proceeds upon orthodox lines, and is a complete, up-to-date summary of modern views upon colloids, suggests that the author's historical researches have been conducted with the same critical judgment, and it seems likely that our conviction that British observers were the first to call attention to colloidal properties is mistaken, though it is probable that Graham worked at the subject independently and without knowledge of Selmi's researches.

## BRITISH ASSOCIATION MEETING.

THE British Association for the Advancement of Science will meet this year at Oxford from Wednesday, August 4th, to Wednesday, August 11th, under the presidency of H.R.H. the Prince of Wales, who succeeds Prof. Horace Lamb in the chair. His address, delivered on the first evening in the Sheldonian Theatre, will be relayed to the town hall, and, if necessary, also to the hall of the Oxford Union Society. Sectional addresses will be given by Prof. J. Graham Kerr (Zoology) on Biology and the Training of the Citizen; Dr. J. Drever (Psychology) on Psychological Aspects of Social Punishments; Prof. H. J. Fleure (Anthropology) on the Evolution of Human Races; and Prof. J. B. Leathes (Physiology) on Function and Design. During the meeting papers will be read on the Value of Tissue Culture in Biology, on the Training of the Zoologist, and on Inheritance of Physical and Mental Characters in Man. A discussion on Secondary Sexual Characters will centre around the respective parts played by inherent cell-organisation and by hormones in the development of the manifestations of sex. Prof. J. S. Haldane will lecture on Acclimatisation to High Altitudes. The sections will meet in the University Museum, the Clarendon Library, and various colleges and schools. Receptions will be held on the evening of August 5th by the Vice-Chancellor of the University and by the Mayor of Oxford, and public lectures have been arranged for every week-day evening during the meeting. Applications for seat tickets should be addressed to the Secretary of the British Association, Burlington House, London, W. 1.

## COLONEL ALCOCK'S RETIREMENT.

Lieut.-Colonel A. Alcock, F.R.S., who in 1907 was appointed director of entomology in the London School of Tropical Medicine, and having reached the age-limit in July, 1924, was invited to continue in his post, when the London School of Hygiene and Tropical Medicine was founded, has now retired. His work has meant so much to the School that it was natural for his friends and colleagues to make some occasion for giving expression to the high esteem in which he was held by those associated with him, and a presentation of a suitably-inscribed loving-cup to him and Mrs. Alcock was made by the School on March 23rd, when Dr. Andrew Balfour wished them many years of continued happiness and assured Colonel Alcock that the School would not forget him. Colonel Alcock had reached the assistant chair of zoology in the University of Aberdeen before joining the Indian Medical Service in 1885, and it was not long before he found proper outlet for his bent in becoming surgeon-naturalist to the Marine Survey of India. After this he was for 11 years superintendent of the Indian Museum and professor of zoology in the Medical College of Bengal. His book on entomology for medical officers, which has passed through more than one edition, was no formal text-book, but was written with the definite aim of clarifying the entomological borderland so as to enable medical men to recognise and follow up the insects and kindred creatures that invade the medical domain. Few books have served their purpose better than this book, whose scholarly writing makes it a pleasure to read and study. The dedication to Sir Patrick Manson, whom Colonel Alcock greatly revered, is in words which are now as applicable to the author himself:—

---

[1] Acta Med. Scandinav., 1923, lviii., 280.

[2] Arch. Int. Med., 1926, xxxvii., 217.

[3] Introduction à l'Étude des Colloïdes. By W. Kopaczewski, Docteur en Médecine ès Sciences, Professeur à l'Institut des Hautes Études de Belgique. Paris: Gauthier-Villars et Cie. 1926. Pp. 226. Fr.15.

> "First he wroghte, and afterward he taughte;
> But in his teaching discreet and benigne."

Colonel Alcock has been succeeded as director of entomology by Dr. P. A. Buxton, but we may express the hope that he will long continue to illumine the subject of tropical medicine by his teaching in public and private.

### THE VIRTUES OF THE ULTRA-VIOLET RAY.

FOR a generation most of us have recognised in a general way the value of the hygienic-dietetic régime in tuberculosis without inquiring very closely into the precise credit to be given to its various factors. Only recently has ultra-violet radiation come to claim a large share in the physiological uplift. At the Cambridge Conference, reported on another page, Dr. James Crocket expressed his opinion that even in pulmonary tuberculosis ultra-violet radiation may prove useful, although he gave a timely warning against regarding it as a substitute for other recognised treatment. In local tuberculosis, where phototherapy has come into wide use, its application is still empirical. At the Harveian Society on March 18th an interesting discussion took place on Treatment by Ultra-violet Rays, which Dr. Halls Dally summed up well by the remark that it was extraordinary how opinions could differ, and that at present our knowledge was very scanty. The well-known views of Dr. Leonard Hill, who opened the discussion, were challenged by Dr. Gordon Pugh, an abstract of whose address appears on page 741. He does not see reason to accept the prevalent idea that light imparts some special bactericidal power to the circulating blood. In his experience the undoubted beneficial effects of the open air are rather due to increased metabolism—from exposure of skin and the breathing of cool air—than to any special virtue in the rays of the sun. Has any new therapeutic principle really been introduced? he asks, or is it that fresh air and surface hyperæmia—those well-established healing agents—are only appearing again in another form? Dr. Pugh's own experiments have not led him to agree with Dr. Rollier's opinion, now so generally accepted, that the more a patient's skin becomes pigmented the better will be the protection against tuberculosis. A close parallelism between pigmentation and favourable prognosis would, of course, indicate that sunlight was the potent agent; but in Dr. Pugh's cases there has been no such parallelism. His opinions may nowadays be thought heretical, but Dr. Hill was right in pleading that they should not be forgotten in the report of the Biological Light Committee of the Medical Research Council. Dr. Hill was far from accepting them himself. Like Dr. Pugh, he said, he had begun by attributing the virtue of the open air to metabolic changes, but investigation of the claims of Bernhard and Rollier had made him modify his views very much, and now he was fully persuaded that light had a very powerful action. It was not unlikely, he thought, that some of Dr. Pugh's successful cases, in which there had been no sunlight treatment at first, had received great benefit from skyshine, which was very rich in ultra-violet rays.

ON March 29th Sir John Rose Bradford was elected President of the Royal College of Physicians of London in succession to Sir Humphry Rolleston, who retires after four years of office. Dr. R. O. Moon was elected assistant registrar.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXVII.—THE TREATMENT OF TETANUS.

### *Prophylaxis.*

THAT prevention is the best form of treatment in tetanus was proved during the war. Even if the disease develop after prophylactic serum, the incubation period is much prolonged, the symptoms are usually mild, often remain localised, and the condition is considerably more amenable to treatment. Consequently, in all wounds likely to have been contaminated with soil or external clothing, especially punctured or lacerated wounds, it is wise to give a prophylactic dose of antitetanic serum. This can be administered either subcutaneously in the abdomen or flank, or preferably intramuscularly in the gluteal region, or in the vastus externus muscle on the outer aspect of the thigh. The initial dose should be at least 500 units (U.S.A. standard); in heavily contaminated wounds, or when several days have elapsed since the injury, 1500 units must be given. The wound itself should be thoroughly cleaned up, all foreign bodies, clots, sequestra, and necrotic tissue being removed. Finally, the wound is thoroughly swabbed with tr. iodi. 1500 units of tetanus antitoxin must be administered intramuscularly at least four hours before undertaking any cleansing or operative measure, as in fresh tissues opened up by operation the absorption of toxin by the perineural lymphatics is extremely rapid, and tetanus has been known to develop within 48 hours.

The effect of a prophylactic dose of antitetanic serum lasts only ten days. If, therefore, the wound remains unhealed, further injections (500 units) may be given subcutaneously at weekly intervals, in order to anticipate the total disappearance of antitoxin from the body, until three or four doses have been administered. With such small doses of serum given subcutaneously at any interval of time the risk of anaphylaxis is negligible. When operations are performed at the site of previously infected wounds, even if soundly healed, it is advisable to give a prophylactic injection of antitetanus serum two days before operation.

### *Early Diagnosis.*

Early diagnosis is of paramount importance. The classical symptoms described in text-books are those of a relatively late stage of the disease when specific treatment will have lost most of its value. The premonitory symptoms that at once should arouse suspicion are as follows:—

Sensation of stiffness in the posterior cervical muscles or in the jaws on opening the mouth widely; cramp or stiffness in the region of the wound; intense headache or backache; general restlessness, profuse sweating, and excessive yawning; sleeplessness, with anxious facial expression; hesitancy of micturition.

Early signs justifying a diagnosis of tetanus are:—

In the vicinity of the wound—muscular rigidity, painful cramps, or spasmodic muscular twitching (if the wound involves an arm or leg, the whole limb may show an occasional twitch). Difficulty or delay in swallowing or in opening the mouth, with increased tonicity on palpation of the masseters or muscles of the neck; increased rigidity of the facial muscles (spastic smile) and inability fully to protrude the tongue; increased reflex excitability—knee- and ankle-jerks, ankle-clonus, or slight muscular twitchings on pressure of the flexor tendons; difficulty in micturition; the occurrence of an occasional generalised spasm.

If any doubt exists it is far better to treat as tetanus; if the diagnosis is mistaken no harm will result.

### *Specific Treatment.*

As soon as the diagnosis is made, the first dose of antitetanic serum should be given intraspinally. Animal experiments and clinical observations have shown that intrathecal administration ensures the antitoxin being brought into the closest possible contact with the nervous tissues involved, and in the shortest space of time.

*Method.*—Lumbar puncture is performed in the usual way, a general anæsthetic being advisable. The quantity of cerebro-spinal fluid withdrawn should exceed by at least 8 c.cm. the volume of serum it is proposed to inject. Serum containing 16,000 to 20,000 units (U.S.A. standard), warmed to body temperature, is administered, either very slowly with a syringe or by the "gravity" method, from a small sterile funnel and tube. High-potency or "concentrated" antitetanic serum should be used (Messrs. Burroughs and Wellcome supply phials of 10,000 units of concentrated antitoxin contained in 10 c.cm. of serum, and the Lister Institute phials of 20,000 units in not more than 25 c.cm. of serum.) A total volume of 30–40 c.cm. of serum can be injected provided that more than this quantity of cerebro-spinal fluid has been evacuated. The foot of the bed is then raised for three hours in order to assist the upward flow of the serum. It is also advisable to supplement the intrathecal injection by giving 8000 units of antitoxin intramuscularly in order to combat any toxin that may still be circulating in the blood stream. Intravenous injections of antitetanic serum tend to cause anaphylaxis and not are advised. The initial intrathecal injection of serum usually gives rise by the following day to a certain degree of "aseptic meningitis." The cerebro-spinal fluid if withdrawn will be found slightly turbid, showing numerous clear and well-defined polymorphonuclear leucocytes. The temperature rises, and the patient may appear actually worse, showing symptoms of meningeal irritation—photophobia and increased muscular rigidity of the neck and limbs. In cases where the tetanus is yielding to treatment, however, these symptoms will disappear in a few days. On the second and third day of treatment both the intrathecal injection (16,000 units) and the intramuscular injection (8000 units) should be repeated. Following this, intramuscular injections only may be continued—8000 units on the fourth day and 4000 units on each of the fifth and sixth days. Subcutaneous doses of 2000 units are then given every other day until the symptoms have abated.

There is practically no limit to the total amount of serum that can be given; I have administered as much as 150,000 units to a single severe case recovering in the course of 18 days. A serum rash appears within seven to ten days of the first dose of serum in most cases, and occasionally facial herpes; as a rule these conditions require no special treatment.

### *General Treatment.*

The patient must be kept in bed in a darkened room with his back to the source of light, which is shaded. Absolute quiet is essential; even a slight noise will often provoke an exhausting painful spasm. Careful nursing is of the utmost importance, and the patient should be disturbed as little as possible. The temperature is taken in the axilla or groin, and when spasms tend to occur frequently, not at all. All dressings must be done quickly and deftly; laxatives given by the mouth are less disturbing than an enema. The nourishment should be fluid—milk and eggs, soup, beef-tea, brandy, &c.—and the patient spoon-fed. When trismus is pronounced, he is given liquid food through a straw or small rubber tube; nasal feeding should be avoided. For the painful spasms the best drug is chloretone given in 20-gr. doses three- or four-hourly; chloral (gr. 30 every four hours) is also useful and in tetanus superior to morphine; bromides are of little value. If the patient is unable to swallow, hyoscine (gr. 1/100) may be given hypodermically or chloretone (gr. 60) administered in solution per rectum; it may be necessary to resort to nutrient enemata, but their food value is very small. When spasms are frequent and severe, chloroform anæsthesia may be induced, especially if the respiratory muscles are affected.

Of other remedies that have been advocated there is no evidence that injections either of carbolic acid or of magnesium sulphate have any curative value.

### *Treatment of the Wound.*

The advisability of surgical measures directed to the wound when tetanus symptoms first make their appearance is doubtful. Some surgeons have advocated opening widely or excising the wound, and when a limb is involved, even amputation—in the hope of arresting the absorption of tetanus toxin. In my experience, surgical operations during the course of tetanus do far more harm than good, and probably, by opening up perineural lymphatics for the absorption of further tetanus toxin, even aggravate the disease. It is safer to abstain from surgical activity. The wound should be syringed gently every three or four hours with hydrogen peroxide. An open dressing consisting of a single layer of gauze soaked in the peroxide should be placed over it during the intervals.

### *Local, Delayed, and Recurrent Tetanus.*

*Local Tetanus.*—In those patients who have received one or more prophylactic doses of antitetanic serum tetanus may develop in a modified form confined to the vicinity of the wound. The symptoms may vary from mere local rigidity of the neighbouring muscles to a persistently tonic condition of a limb. Intermittent and spasmodic contractions may occur in the affected part. In all but the mildest cases, it is advisable to give an initial intrathecal injection (10,000 units) of antitoxin, followed by daily intramuscular injections of 8000 units until the condition subsides. The prognosis is good, but in a few untreated or inefficiently treated cases the tetanus becomes generalised.

*Delayed Tetanus.*—Tetanus may sometimes develop weeks after the original wound has healed, or the disease may follow some slight operative procedure and even a local injury. Recurrence of septic infection in a wound previously healed has also been known to be followed by tetanus. I have seen subacute generalised tetanus develop six months after a gunshot wound of the knee; the patient had received three prophylactic doses of antitoxin at weekly intervals following the wound and made a good recovery. The onset of delayed tetanus may be insidious and the condition may be general or remain localised. Trismus and neck rigidity has been known to remain slight for days and even weeks. As regards treatment, the principles detailed above should be applied according to whether the condition be general or local. The prognosis is good.

*Recurrent Tetanus.*—Occasionally in a patient who has previously suffered from tetanus as the result of a wound, tetanic symptoms may recur following an operation on the wounded area long after it has healed. The patient who has suffered from tetanus is never really out of danger while any foreign bodies or sequestra remain in the body. Tetanus bacilli have been cultivated from material removed from a wound as long as two and a half years after the injury. In cases of recurrent tetanus, as soon as the patient has recovered the wound should be excised and any foreign bodies and sequestra removed, cavities thus made being allowed to granulate up.

It is advisable before operating on a wounded area in a patient who has previously suffered from tetanus to give 15,000 units of tetanus antitoxin, after appropriate desensitisation, two days before operation.

### *Anaphylaxis.*

In all cases in which an interval of longer than ten days has elapsed since a previous injection of serum (including those who are likely to have received a dose of horse serum prior to the present illness), it is advisable to apply desensitising measures before giving a large dose of serum. Such anti-anaphylaxis is best induced by the method of Besredka and Friedberger.

6 c.cm. of the serum is diluted with 50 c.cm. of normal saline; 1 c.cm. of this mixture is injected intravenously; four minutes later this is followed by 3 c.cm. of the diluted serum, two minutes later by 10 c.cm., and after a further two minutes by 25 c.cm. Then in 15 minutes the full dose of serum may be given intrathecally, intramuscularly, or subcutaneously. The intravenous injections of the dilute desensitising serum can be given from a funnel and tube, the latter being pinched and liberated only to allow the required amount of diluted serum to escape into the vein.

Intrathecal injections are much less liable to be followed by anaphylaxis than are intravenous ones; the serum is not absorbed so quickly from the subarachnoid space into the general circulation as when injected directly into a vein. Through this slow absorption the patient probably becomes desensitised.

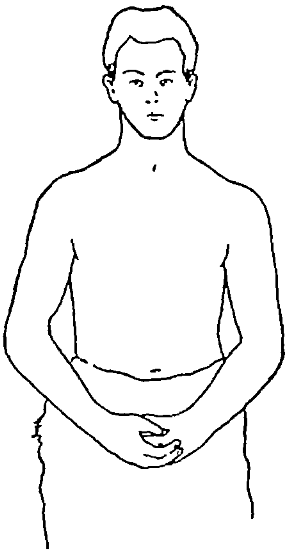
## THE IMPORTANCE OF CORRECT POSTURE IN TREATMENT BY IMMOBILISATION.

BY T. E. HAMMOND, F.R.C.S. ENG.,
ASSISTANT, SURGICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE.

EVER since Hilton delivered his famous lectures on Rest and Pain, the placing at rest as far as possible of a diseased or injured organ has been regarded as a fundamental principle in treatment; if it is neglected, the best functional result is not attained. It often happens that a too zealous application of any form of therapy leads to its abuse, and treatment by rest is no exception. The prolonged rest of organs which are injured or whose nutrition is impaired does undoubtedly at times give rise to disastrous results. This was seen when fractures of the long bones were fixed by splints which were not removed until firm union had taken place.

FIG. 1.



The position of rest.

The resulting limitation of movement in neighbouring joints was out of proportion to the primary injury, and its degree was largely dependent on the duration of the immobilisation. The poor functional result was attributed to the prolonged rest. Consequently, there has been a recent tendency to decry its importance, and even to regard it as harmful. In the nerve lesions that were so common during the war, recovery of power was rarely seen in the muscles, in spite of perfect nerve surgery, until the teaching of Sir Robert Jones on the necessity for relaxing paralysed muscles was appreciated. By relaxation is meant the placing of a muscle at rest so that no strain is thrown upon it. When this line of treatment became popularised, the adhesions that sometimes developed were more marked than in the cases where it had not been carried out. Here again rest was condemned, but wrongly so, as adhesions did not form in cases where relaxation was properly applied.

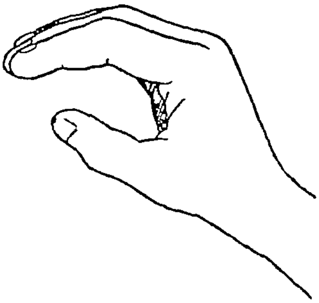
The true cause lay in failure to appreciate two essential principles. The first—with which I shall not here deal—is that complete rest is unnecessary after all inflammation has subsided or after repair has taken place, when activity, so graded that it is well within the capacity of the organ to perform and not of sufficient duration to induce fatigue, should be resumed. The second and more important is that, when one structure is placed at rest, no strain should be thrown upon any other. When an abnormal posture is taken up, the stretching of the muscles and ligaments leads to lengthening of the former and a constant strain upon the ligaments, which are inelastic. Paresis of the muscles follows, and a chronic irritation around the attachment of the ligaments that ends in an aseptic inflammation and the formation of adhesions. These are all the more marked if the nutrition of the limb is damaged or any septic process is present. T[illegible]irment of function becomes most evident in [illegible], where the slightest derangement interferes with accurate and finely coördinated movements. Consequently, the harmful effect of any line of treatment will be soonest appreciated here, and it is largely with the application of rest in the treatment of lesions of the hand that this article deals.

### *The Position of Rest.*

There is one position, the position of rest, in which all muscles, tendons, and ligaments are relaxed.

This position, which is assumed during ease and sleep, is that from which movement in any direction can be most easily started. Though varying with each individual, it approximates to a standard, and may for all practical purposes be described as follows.

FIG. 2.



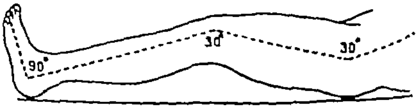
The hand in the position of rest.

In the erect attitude, when no accessory means of support is made use of, the forearm rests on the prominence formed by the great trochanter, which, by taking part of the weight, relieves the strain upon the muscles and ligaments. The upper arm is abducted 30° at the shoulder and is rotated inwards; the elbow is flexed to 120°; and the wrist is dorsiflexed 30° with the hand midway between pronation and supination. (Fig. 1.)

In the hand (Fig. 2) the fingers are flexed 30° at the metacarpo- and inter-phalangeal joints. The thumb is abducted 30° in a plane at right angles to the palm and is flexed 30° at both joints. Four main arches are present—a proximal and a distal transverse, and an inner and an outer longitudinal. The *proximal arch*, formed by both rows of the carpus and the bases of the metacarpals, has a dorsal convexity most prominent over the junction of the third metacarpal and the os magnum. The *distal arch*, formed by the heads of the metacarpals and most prominent over that of the third, is continued forwards to the tips of the fingers. With flattening of the latter arch the power of flexion of the fingers is lessened, with flattening of the former that of the thumb. The *outer arch*, formed by the outer portion of the carpus and thumb, arises at the scaphoid and passes forwards to the tip of the thumb. The *inner arch* is formed by the metacarpals and the phalanges of the fingers. The summit of both is over the heads of the metacarpals.

In the lower limb (Fig. 3) the hip is flexed 30° and is slightly abducted and everted, the knee is flexed 30°, and the ankle is dorsiflexed to a right angle.

FIG. 3.



The leg in the position of rest.

The position of rest is maintained to some extent by the ligaments and fasciæ, but chiefly by the postural tone of the muscles, the importance of which has been pointed out by Sir Charles Sherrington. It is sometimes stated that tonus is found only in the antigravity muscles. This is not the case, for, while it exists to a greater extent in these, it is also found in the opposing muscles. This is seen in lesions of the median and ulnar nerves, where, although the wasting of the muscles of the hand is partly responsible for the deformity, this is due chiefly to the unopposed tone of the extensor muscles and can be corrected by very slight force.

The position of rest can be maintained over long periods without the slightest discomfort or fatigue. This can be said of no other posture. Were the hand to be immobilised in this position for several weeks, there would be no discomfort, and on removal of the splint full and forcible contraction of the muscles could immediately take place, showing that no strain had been thrown on any structure. Any other posture could only be maintained either by contraction of the muscles or by passive force, being associated with hyper-relaxation of one group of muscles and ligaments and stretching of the opposing group. Extension of the fingers causes an ill-defined feeling of strain over the palmar surface that passes into the forearm when the wrist is dorsiflexed, and is relieved by taking up the position of rest. It is also felt to a lesser degree over the dorsum, when the wrist and fingers are flexed. Were the hand to be immobilised in either position for some weeks, a dull pain would be present, and after removal of the splint there would be a slight though temporary weakness due to continued tension on the muscles and ligaments.

The knee may be taken as an example of the larger joints. When immobilised in the fully extended position there is a feeling of discomfort over the back of the joint which passes off when it is slightly flexed. In the former case the knee has been *placed at rest*, in the latter in its *position of rest*, the essential difference being that while the latter included the former, it also means that no strain is thrown on any structure round the joint, a point of great importance. Those who have had to stay in bed for a long period will have learned to appreciate the ease that follows the placing of a pillow under the knees, which places the legs in their normal position of rest.

In 1916 my attention was first drawn to the importance of posture in treatment. When injured organs are kept in the position of rest, not only does any inflammation present show a greater tendency to subside, but adhesions are not so extensive and can be more easily broken down. The most intractable cases are those in which it is evident from the deformity present that, though treatment by rest had been carried out, treatment in the normal position of rest had not. In the case of the hand, for example, the fingers had been fully or even hyperextended, with flattening of the palm and obliteration of the arches. After fractures of the femur much limitation of movement is generally seen when the knee has been kept extended; whereas if about 30° of flexion have been allowed, full movement is often present.

It can, therefore, be laid down as an axiom that in all cases of injury or inflammation, when rest is advisable, the injured and neighbouring parts must be placed in their normal position of rest unless some definite contra-indication is present—*e.g.*, when, in fractures of the lower end of the humerus, the elbow has to be fully flexed. When a joint is involved in some inflammatory process, it becomes slightly flexed. This flexion increases later and so a definite deformity arises. In the early stages of all inflammations complete restoration of function should be the aim, which is best attained by keeping the joint in its position of rest. As the tendency is towards a flexion deformity, some have advocated that the joint should be held fully extended. I am certain, however, that such advice is wrong. When tuberculosis of the knee is treated with slight flexion, the inflammation tends to subside more quickly, abscesses are less likely to form, and the end-result is often good; when treated with full extension, the functional result is poor and complications are more common.

*The Position of Ankylosis.*

When it is obvious that destruction of the joint has taken place, limited movement is to be expected. In such cases the joint should be placed in the position that would give the best function should ankylosis occur. In the past there has been much controversy over the various positions that have been advocated. Yet it is quite easy to find out the optimum position by fixing one's own joints in plaster-of-Paris. In my opinion it generally corresponds to the position of rest.

Limited movement at a joint must necessarily give rise to some disability which will be partly compensated for by the increased movement that takes place in the neighbouring joints, especially if the patient is in early life. Recently I saw a pensioner, aged 25, who had a cross union between the ulna and radius of seven years' duration. He was unable to pronate or supinate the hand when the elbow was fixed. Yet when the latter was free, the rotation of the hand was almost equal to that seen in the normal adult, owing to the increased rotation acquired at the shoulder. The position of an ankylosed joint should throw as little strain as possible on the neighbouring joints, a point of much importance in the lower limb, where the constant strain is apt to set up an arthritis.

When the thumb and fingers are ankylosed in the position of rest, not only can objects be easily grasped, but the remaining digits can be readily opposed. Dorsiflexion to 30° is essential at the wrist, as full forcible contraction of the flexors can take place only in this position. The position of an elbow should depend largely on the occupation pursued. In the labouring classes flexion to 100° with the hand slightly pronated, and in women flexion to 75° with the hand slightly supinated, are probably best. When circumstances permit, it is well to fix the normal elbow in plaster for a short time, so that the patient can appreciate what is happening; full consideration should always be given to his views. Limited movement at the shoulder is partly compensated for by the movement of the scapula on the chest wall. When the shoulder is ankylosed with the arm abducted 60° and the elbow in front of the line of the body, the arm can be brought to the side, and abduction to 120° with a certain amount of flexion and extension are possible.

Since the lower extremity has to support the weight of the body, strength and stability are essential. Much time is, however, spent sitting down and at rest. When the hip is ankylosed in the position of rest, full extension and flexion to 70° may seem to be present. But this is only apparent and takes place through the movement of the spine. As a result, on standing the hip and neighbouring joints are in the position of rest; on walking the thigh can be brought into line with the body; on sitting moderate comfort is possible. When ankylosis takes place in full extension, as is sometimes recommended, sitting is most uncomfortable, and on standing there is constant strain upon the neighbouring articulations. The knee should be ankylosed flexed 30°, as this allows full movement at the ankle and hip on walking; when ankylosis takes place with full extension, dorsiflexion at the ankle is limited. The ankle should be ankylosed at a right angle, as the modern heel allows the knee and hip to be maintained in the position of rest on standing; and, as the whole of the sole of the foot is in contact with the boot, the weight is transmitted in the normal manner.

## PENSIONS FOR HOSPITAL OFFICERS AND NURSES.

### II.*

IN the preceding article the general outlines of the proposed scheme to provide pensions for hospital officers, including nurses, were given; we have now to come down to actual figures, dealing first with individual cases and finally with the total cost as it would affect the institutions.

Let us look first at the scheme from the point of view of an officer of the senior class, entering at age 20 upon hospital service, with a salary of £100 and emoluments of £30. At the outset he would pay £6 10s. a year out of his salary, and the hospital would pay £13 in his respect. It may be assumed for purpose of illustration that the officer's salary gradually rises by increments of £10 until he is receiving £200 a year at age 30—i.e., £230 in all at that point, and that thenceforward he enjoys his increases of £20 and, eventually, increases of £30, so that he reaches [illegible] in all by the time he is aged 50. We his annual contribution gradually rising pari passu with the salary to £39 a year, while the contribution of the hospital would gradually mount to £78 a year. As each addition to salary came into being, so would a new or increment policy be automatically effected. Even in the case of an Endowment Assurance, this would necessitate no medical examination after the initial one, and, of course, where the Deferred Annuity option was selected no examination would be necessary at any time, seeing that the option does not carry with it a death benefit in the way in which an Endowment Assurance does, for the amount paid at death really represents only the accumulated value of the payments which have been made.

---

* Part I. appeared in THE LANCET last

Now, that initial annual payment of £19 10*s.* predicated here—viz., the £6 10*s.* from the officer and the £13 from the hospital—would provide for the hospital officer a Profit Endowment Assurance of £828, payable at age 60, or at previous death, with estimated Reversionary Bonuses gradually accruing and amounting at the end of the period to a further £558. As each increase in his salary throughout his service, carrying with it (as it would) the increased contributions, would gradually augment the amount insured and the accompanying bonuses, he would see the initial policy of £828 increased stage by stage to a total of £2689, and the ultimate bonuses standing added to the Policy at age 60 similarly increased to £1499. There would thus be a grand cash total at retirement of £4188, which sum would, if the pension option were selected, purchase an Annuity from age 60 of £354.

Under the foregoing Endowment Assurance option it must be clearly understood that the death benefit throughout the service is one of very considerable magnitude; to give an idea of its amount, if death occurred at age 35, there would be probably some £2000 payable to those whom he left behind him; if death occurred at age 40, the sum would be £700 or £800 more than that. If the officer, instead of selecting the Endowment Assurance option preferred to take that of the Deferred Annuity with return of premiums in the event of death, he would, if he lived out the full period, have amassed at the end of the time £5111, which would provide a pension of £441 10*s.* from the attainment of age 60 until death. In other words, by forgoing the valuable death benefits of the Endowment Assurance policy, and preferring a Deferred Annuity, a larger eventual pension is secured. This is, therefore, a better option for the man who is unmarried, or rather—an important proviso—for the man who is confident that he will remain unmarried throughout his service!

In a similarly typical case in the clerical or dispensing staff, where the salary and emoluments might run from £130 up to a limit of, say, £480 at age 50 or over, we have an initial sum of £6 10*s.* payable by the official and £13 payable by the hospital, gradually increasing as small additions are made, until at age 50 the contributions would be £23 10*s.* for the officer and £47 for the hospital; these would serve to produce an ultimate cash sum, represented by the Endowment Assurance policies and bonuses, of £3222, with a pension option of £272. The Deferred Annuity, while again giving far less if death occurred before pension age, would yield a cash sum of £4029 at maturity and so provide a correspondingly high pension.

As a third test we may take the case of a member of the nursing staff, beginning as a staff nurse with an average salary of £60 and emoluments of £50, passing through the stages of a ward sister with a salary gradually rising to £115, with emoluments of £60, and thereafter becoming a home sister, and eventually an assistant matron with a finishing salary at that stage of £220, with emoluments of £80. We may follow her career further, until, as a matron, she finishes with a salary at £300 and emoluments at £150. At the outset we will credit her with £20 to represent the accumulations made during her period of training, and will apply them in the form of [illegible] premium to increase the amount of her [illegible] taking this into account, and the fact that she begins by paying £5 6*s.* 8*d.* a year, where the hospital pays £10 13*s.* 4*d.*, her contributions gradually rising as she progresses until finally she is paying £22 10*s.* and the hospital £45; and we see that the result is that by age 55 there will be available a total sum of £1571 made up of the Endowment Assurance policies and bonuses, with a cash addition of £224 made up of the contributions paid during the few final years of service where the term is too short to admit of further increment policies under with profit Endowment Assurance tables, and thus bringing the total cash to £1795, which total in turn would provide an annuity of £118 6*s.* Here again the Deferred Annuity option would give a greater pension at the expense of lessened death benefits; for it would give an ultimate cash sum of £2036 instead of £1795. Moreover, in such a case as this illustration, choice would as a rule wisely fall upon the Deferred Annuity, for the woman's problem differs from that of the man unless she has others definitely dependent upon her. Indeed, nearly all nurses are likely to take Deferred Annuities since, for the rank and file, pensions to begin at age 55 are so expensive that the amounts will be none too great in any case.

### *The Cost to Hospitals.*

To get an idea of the cost of the scheme, if it were adopted as a whole, an example may be given of the figures as they would be applicable to a typical general hospital in the metropolis, containing between 500 and 600 occupied beds as an average. The number of employees within the limits of the scheme in such a case would be about 272, and the total salaries and emoluments £38,300, so that the hospital's annual contribution would be £3830. Taking as an instance a small institution, say, a special hospital with between 30 and 40 average occupied beds, we should find 22 employees within the scheme, with total salaries and emoluments of £3191, and an annual cost to the hospital of £319.

The memorandum, which was drawn up by King Edward's Hospital Fund for London and three other associations and circulated amongst the hospitals, points out that in the year 1924 there were 64 voluntary hospitals in London with surpluses altogether amounting to £280,000, and 54 hospitals with deficits amounting to £118,000, and certainly the statistics of the last five years do show that the number of hospitals with surpluses is steadily increasing and the number of those with deficits is steadily decreasing. There is, however, no burking the fact that, as we stand to-day, there are nearly as many hospitals with deficits as there are with surpluses, and no general statement that the hospitals, as a whole, are in an improved position is very comforting to those whose accounts are still upon the wrong side. It is true that in 1920, 1921, and 1922 the voluntary hospitals of London showed a net aggregate deficit for the year, first of £385,000, then of £214,000, and then of £177,000, whereas in 1923 there was a net aggregate surplus of £227,000, and in 1924 one of £162,000, from which the general improvement is evident, even though the 1924 figures indicate that improvement is not yet to be counted upon too exactly. The individual hospital, however, must cut its own coat according to its cloth.

One is compelled to come to the conclusion that for a very large number of hospitals the whole scheme in its entirety is an ideal which is at present beyond their powers, unless they are to be in some way very greatly assisted from outside sources. This, however, is not to say that it is impossible for them to make a beginning, and it would seem better to make that beginning from the top—that is to say, with the senior officers, matrons, and so on—rather than at the other end where you have the nursing probationers.

Looking at the figures with regard to the nursing class we find that a careful analysis has been made of 500 probationers who entered hospital for training between 1908 and 1914. Of these no less than 194 got married, 61 dropped out from death, ill-health, or from one cause and another, and only 245, less than half the total, went on with nursing work. Even of that number only 40 actually received hospital appointments, the rest obtaining appointments in such spheres as nursing homes or schools, or going into welfare work or missionary work, or the Army Nursing Services.

Such figures as these force a realisation that this large part of the scheme, involving as it would do an immense organisation and great difficulties with regard to the cost, both for the hospitals and the individuals, must really miss fire so far as more than half the persons embraced in this category are concerned. Those who frame such schemes as this are almost invariably attracted by the ideal of completeness, and always there is reluctance to admit that completeness is not possible; but, where the resources of a hospital are very limited, it is this end of the scheme that must be abandoned for the present as being the least effective use of the available money. To do something to place upon a safer footing the eventual provision for the old age of the senior officials, those who are giving their lives to hospital work and are the teachers of this branch of the profession, is something to effect which every possible strain must be borne.

With regard to the nursing profession, the view of one who comes from other spheres of work to the consideration of the matter is that the wages paid to women are too low. What are called emoluments in this connexion are simply such board and lodging as we all give in our homes to the ordinary domestic servant; but to domestic servants to-day we pay far higher wages than are paid to nurses working in the hospitals.

---

# THE TUBERCULOSIS CONFERENCE,

## CAMBRIDGE, MARCH 25TH–27TH.

A JOINT conference of the Tuberculosis Society and the Society of Superintendents of Tuberculosis Institutions was held at Cambridge from March 25th to 27th.

The opening session was devoted to a discussion on

### *Ultra-violet Rays and Tuberculosis,*

introduced by a paper read by Dr. JAMES CROCKET, medical superintendent of Consumption Sanatoria, Scotland. Dr. Crocket gave a systematic account of the four groups of radiation known to have therapeutic properties, the lamps in general use, and the physiological and therapeutic effects of their action, the suitable and unsuitable types of case, and the general signs of intolerance. Contrary to the general opinion, he had not found ultra-violet radiation to be necessarily contra-indicated in pulmonary tuberculosis. With adequate precautions, especially with care to have the patient in the recumbent position and exposed to as little risk of fatigue as possible, improvement had been effected in 86 per cent. of cases as compared with 67 per cent. improvement by ordinary methods. Dr. Crocket stressed the point that ultra-violet radiation should never be allowed to become a substitute for the recognised hygienic treatment of tuberculosis. He also thought that it was high time we found a more comprehensive and accurate descriptive term than ultra-violet radiation and suggested phototherapy or electrotherapeutic radiation. In the discussion which followed the two most important points emphasised were those of immobilisation of the part and ventilation of the lamp room. Apparently it has been the practice in some institutions to remove the splintage from limbs during light treatment and thereby undo the good effects of immobilisation. Ventilation of the lamp room was considered a much-neglected point.—Dr. J. G. JOHNSTONE (Heatherwood) stated that in the course of visits paid to many institutions in Great Britain and on the continent he had found a great neglect of this all-important principle. Lamp rooms sometimes had no ventilation at all, and tuberculous patients were submitted to a temperature which produced a condition little short of heat-stroke. He considered that it was this overheating and lack of ventilation which was responsible for the recorded cases of hæmoptysis following light treatment. From the discussion it seemed clear that institutions installing a light plant must not in the future be satisfied with devoting some odd waste corner of the building to this object, but must make the same careful preparations as were necessary in building an operating theatre or other special department. The important and much neglected question of daily measurement of the ultra-violet rays and the various methods in use for this purpose seemed entirely to escape the notice of the conference. It would appear to be one of the next steps in getting really accurately controlled results of treatment.

Later in the afternoon Dr. G. MARSHALL, assistant physician to the tuberculosis department of Guy's Hospital, read a short paper on

### *Tuberculosis and Pregnancy,*

dealing with the subject from the point of view of the effect of the pregnancy on the tuberculosis. Of the cases of pulmonary disease referred to his department by the antenatal clinic at Guy's, Dr. Marshall had collected 13 non-tuberculous and 25 tuberculous cases, most of them occurring in the early months of pregnancy before the mechanical factor in causation was of much account. The majority of the tuberculous cases had been made worse by the pregnancy, and Dr. Marshall considered that modern opinion had reversed the old dictum that pregnancy was a good thing for the tuberculous girl. It seemed possible that there was a biochemical factor at work in these cases which was not yet understood. His opinion, in the light of the experience so far gained, was that wherever possible sterilisation of the patient should be effected, and where the pregnancy was terminated by Cæsarean section this was not difficult to do. In the subsequent discussion there was a general consensus of opinion that pregnant women reacted exceptionally well to sanatorium treatment, that labours were generally easy, and that in considering the future of the patient the ordinary rules of prognosis in tuberculosis must prevail. Cases were quoted by various speakers showing both the bright and the dark side of this clinical picture, and it was evident that personal experience of different types of case had led tuberculosis experts to hold divergent views on the subject. Probably this method of deduction from particular groups of cases contains an old fallacy—the difference in the economic and environmental factors in different groups of cases. Obviously the hospital out-patient class of woman is in a very disadvantageous position psychologically, economically, and environmentally, as compared with the middle-class woman or even with the agricultural labourer.

On the following morning the conference turned its attention to a consideration of

### *Catarrho-pyogenic Infections and Tuberculosis,*

the subject being introduced by Sir HUMPHRY ROLLESTON. The inter-relation of these two types of infection raised many difficult questions. The time relations of the two infections, the old "dualistic" conception of consumption of Virchow's day before the discovery of the tubercle bacillus, the delayed appearance of the tubercle bacillus in closed lesions all combined to make the problem a very thorny one, and the speaker thought it unwise to adopt Dr. Batty Shaw's appeal for a new nomenclature in the present state of our knowledge. Such a course might obscure the primary underlying factor of the disease.—Dr. BATTY SHAW continued the discussion. He based his argument on the well-known mortality curve for tuberculosis which showed a sharp rise in infancy, an equally sharp fall after 5 years of age, a flat low plateau until the age of 10, and then a gradual rise through the period of puberty, adolescence, and early adult life. In this second period of high mortality Dr. Batty Shaw considered that catarrho-pyogenic infection played a most important part, acting as a liberator of the tubercle bacillus. The latter did not, when unassociated with catarrho-pyogenic organisms, produce pus formation, caseation, and resultant hæmoptysis. The discussion which followed these two papers ranged over many different aspects of the subject and obviously no conclusion was possible. Most speakers agreed that the catarrho-pyogenic organisms had to be reckoned with as causative factors in tuberculosis, but exactly how and when they entered the field it was premature to decide. Most of the evidence produced was purely clinical and therefore of necessity incapable of being put to an accurate scientific test.

The rest of the session was given up to a paper by Sir **StClair Thomson** on the indications, technique, and results of

*Galvano-Cautery Treatment of Tuberculosis of the Larynx.*

He gave the results of 14 years' observation of cases of phthisis at Midhurst and recorded his figures as regards both incidence of laryngeal disease and galvano-cautery treatment. He insisted that a preliminary period of three months' observation was essential before local treatment of the larynx should be attempted. When this rule was observed the results were striking. Of all patients seen at Midhurst 17·5 per cent. showed laryngeal involvement, 16·6 per cent. of the latter proved suitable for galvano-cautery treatment, and of these again 64 per cent. showed arrest of the lesion after treatment.—In the discussion which followed Dr. R. R. **Trail** (Midhurst) emphasised the value of a laryngologist's report in prognosis of cases of pulmonary tuberculosis. As regards local cautery treatment, he believed the economic factor and the personality of the laryngologist were most important, the former because of the long preliminary period of observation in sanatorium which was necessary, the latter because the emotional excitement of the tuberculous patient who had to undergo cauterisation needed careful and reassuring handling.

At the afternoon session Prof. S. **Lyle Cummins** read a paper on

*Sanocrysin.*

He considered that rightly used the drug had some beneficial action. He discussed the various problems associated with its administration—viz.: (1) the effect of sanocrysin in liberating tubercle toxin, (2) the gold-ion toxicity of the drug, (3) the accessibility of the tuberculous lesion, (4) the resistance of the patient, and (5) the elimination of the drug from the body. Given a good general condition and a controllable temperature, Prof. Cummins thought the drug was definitely useful, but there were many cases where its use was contra-indicated. Radiograms were essential in interpreting its effects. Dosage was still in its experimental stage; in apyrexial cases he began with 0·25 g. and in pyrexial cases 0·2 g. Inman's classification based on the toxæmia factor was most useful in selecting cases. Prof. Cummins also described the technical details of administration, and stated that it was not uncommon for patients to be made worse for the first fortnight after treatment was instituted and then steadily to improve. Pyrexia, anorexia, giddiness, and even vomiting were not uncommon at first, but passed off. The really serious danger signals were (1) sudden reduction of urine, (2) stomatitis, (3) intestinal disturbance, (4) a tendency to sweating, and (5) persistent albuminuria.—Dr. F. G. **Heaf** described a series of cases he had treated with small doses beginning with 0·1 g., and stated that he believed the small dose method was the most useful.—The discussion on sanocrysin was very short, the conference evidently feeling that the data were too few for general discussion, and the session terminated with a demonstration by Dr. **Parry Morgan** of his special type of artificial pneumothorax apparatus.

The last session of the conference, on Saturday morning, was spent in considering artificial pneumothorax technique and apparatus. Various new t[illegible]paratus were described and end-results (especially in children), and the problems of gas embolism, pleural shock, &c., discussed.—There were also three short communications of very considerable interest from Mr. H. **Morriston Davies**, Dr. S. **Vere Pearson**, and Dr. L. S. T. **Burrell**.—Mr. **Morriston Davies** explained the use and value of phrenic nerve evulsion associated with artificial pneumothorax, by means of which the effect of collapse therapy could be supplemented by paralysing and thereby raising the diaphragm, and resting more efficiently the affected lung and rendering pleural effusion less liable to complicate matters. Dr. **Pearson** described the phenomenon of mediastinal bulging following collapse therapy. This was frequently found to be present when the patient received more gas at a refill than was anticipated, and on examination by radioscope the gas was found to compress the lung to a very small extent. In these cases there was frequently bulging in the posterior mediastinum, which could be seen on the fluorescent screen in the right oblique position, possibly associated with displacement of the middle mediastinum and sometimes, though not always, giving rise to undue dyspnœa. In this connexion it may be noted that the various phenomena and mediastinal movements were briefly described by Prof. Rist, of Paris, at a discussion at the Royal Society of Medicine a year ago. Dr. **Burrell** gave statistics showing the prevalence of pleural effusion in 309 cases in which he had induced artificial pneumothorax. In approximately 41 per cent. of cases this complication had been found to occur sooner or later. Various mechanical explanations had been brought forward to account for the complication, but Dr. Burrell thought that the cause was to be found in the reaction of the tuberculous foci in the lung and pleura, since effusion only rarely occurred in cases of collapse therapy performed for non-tuberculous disease of the lung.

# Public Health Services.

## TYPHUS FEVER IN ST. HELENS.

The case of typhus fever notified from Sunderland is the first to be brought to light since the small outbreak of this fever which occurred in St. Helens during August and September, 1924, and is described by Dr. Frank Hauxwell in a recent report. He reminds the health committee to which it is addressed that in 1875 typhus fever caused no less than 1500 deaths in England, that it is still prevalent in Eastern Europe, especially in Russia, and that "it is still not uncommon in Ireland." The previous outbreak reported in England was in Birkenhead in February to March, 1922, when there were 12 cases, three of which were fatal. The usual carrier of infection is the body louse, but fleas, bugs, and head lice also serve. Lice after absorbing infected blood retain their infectivity for three or four days, and should they lay eggs during this period the insects hatched from these eggs may transmit the infection. To how many generations this may be carried is, Dr. Hauxwell states, not yet known. The first St. Helens case was discovered on August 12th, when a girl of 14 was sent to the isolation hospital with the notification of measles. The symptoms suggested typhus and the diagnosis was confirmed by Dr. W. Hanna, medical officer of the Port of Liverpool. The girl died three days after admission. On further inquiry the father was found to be under treatment for influenza and to be an undoubted case of typhus. He was removed to the hospital and recovered. Another child from the same house had contracted an illness a month previously, for which she had been treated for pneumonia in the Providence Hospital, whence she was discharged cured on August 10th. An examination of her blood left no doubt that she had suffered from typhus, and was the first known case of the outbreak. The home of this family was not in bad condition structurally, but was verminous.

On August 25th another girl in this family took the illness and recovered. On the same day the mother became ill and died a fortnight later The other three cases were a sister-in law and her son and a contact The outbreak affected in all eight persons, of whom four died, and was confined to three households within 60 yards of one another One of the points noted was the reluctance of the contacts to admit feeling ill Thus the sister-in law said she was perfectly well until she had a temperature of 103° F, and was a well marked case She was removed to hospital the same day and died five days later It would appear, therefore, to be necessary to take the temperature of contacts and not trust to their expressions of well being No cause could be suggested for the outbreak, but the neighbourhood affected was one in which Irish visitors are not uncommon.

### THE FIRST SCHOOL MEDICAL REPORT

The annual reports of school doctors are (or ought to be) human documents, addressed to the lay public through their education and public health committees, showing the progress in the well being of school children deducing from past experience the road along which progress has been made, and outlining the route for further advance Each committee looks to its expert medical adviser for guidance in the direction in which further efforts should be concentrated, and honest doubt is arising whether the time spent over routine weighing and measuring of all children or on duplicated examination of teeth by doctors and dentists is time well spent Apart from remedial work, advance is to be seen in the rapid decline of personal uncleanliness and of dirt diseases associated with the modern tendency towards short hair, loose neckwear, and lighter and shorter clothing The year 1924 was noteworthy for the wide outlining of excellent schemes of betterment more open-air schools and classes were advocated, extensive preparations were being made for supervision of abnormal children, games, orthopædic and special centres were being planned, when Circular 1371 intervened and the surveyed road of advance will now require re-surveying before engineering can begin In the first report for 1925 which has reached us Dr A H G Burton, of Ilford, laments that his hope for an open air school has not been realised, nor that for a centre for mentally defective children, nor that of an orthopædic centre for treating the 311 children requiring such attention In Ilford there are 185 pre-tuberculous children for whom no special provision is made, yet the high cost to the country of treating the case of developed tubercle compares badly with that of preventive open air classes and schools. It takes long for economists to appreciate that prevention is the cheaper and sounder method. Credit is due to Dr Burton not only for his early report, but for the excellence of the results shown in his routine work.

### MENTAL HOSPITAL REPORTS

THE *Royal Albert Institution for the Feeble Minded*, instituted in 1864 for the benefit of the feeble-minded of the Northern Counties, has issued its sixty first annual report, which was approved by a general meeting held at the Town Hall, Rochdale At a public meeting held the same evening Lord Richard Cavendish stressed the voluntary basis of the Institution and the care devoted to the teaching and training of the inmates as well as to their occupation and amusement Since 1870 1386 patients of both sexes have been admitted, of whom 10 per cent. have become practically self-supporting under friendly supervison Scarcely any case leaves the Institution unimproved Accommodation has now been provided for 800 patients in the main building and its dependencies. Employment on the estate and farmlands of 277 acres provides healthy occupation and there is a dairy farm and farm colony for 10 youths who work on the land or tend cows, pigs and poultry Industries and handicrafts are carried on in a system of workshops. The girls assist in a variety of domestic occupations. Dr W H Coupland's eleventh medical report mentions a total of 798 patients, 536 males and 262 females. Fifty new patients were admitted during the year and 83 cases discharged, while 27 (15 males and 12 females) had died This exceptionally high death rate followed an exceptionally low one in the previous year, the average mortality of the past 25 years not having exceeded 2·55 per cent of residents An epidemic of influenza had involved 240 patients and 16 of the indoor staff, amongst whom was a charge nurse who died. Besides influenza, outbreaks of German measles, measles, chicken pox, and whooping-cough had seriously hampered the special training arrangements of Miss Gresham and her staff of teachers. The open air school recently added had proved valuable The useful work done in this Institution continues to retain the benevolent interest of the northern public

The 113th annual report of the *Royal Hospital at Morningside, Edinburgh*, records a successful year of work in 1925 on an average of 830 resident patients drawn from all classes of the community and including a high percentage of voluntary boarders In addition to the four nursing homes in the suburbs for the use of patients under their own medical attendants each adapted to its special type of case, a convalescent home in the country is to be opened this year A mental out-patient clinic at the Royal Infirmary is to be opened this month to investigate and advise on all sorts of difficulties and complaints in which mental instability or weakness is believed to play a part. Here the ideal of prevention will be aimed at Possibly to be run in conjunction with this clinic, which will have no infirmary beds at its disposal the managers hope to open a "Jordan Burn Hospital" to provide for about 48 cases of early and mild forms of mental trouble among the hospital patient class A public appeal is to be made for funds to finance this extremely desirable institution

The *Aberdeen Royal Mental Hospital* has about 800 certified patients and 80 voluntary boarders The recovery rate for 1925 was 27·7 per cent. and the death rate 6·88 per cent. No more cases of typhoid occurred, and the extensive search for a carrier responsible for the 1924 cases met with no success A visiting dental surgeon was appointed during the year and an occupational therapy department was opened A graduate of the College of Occupational Therapy in Philadelphia was appointed instructress and the department appealed at once to a large number of patients The medical superintendent remarks that "it was most instructive to observe the gradual development of interest in some melancholic and demented patients" The work includes the making of rugs, raffia and cane-baskets, teapot stands, trays, toys, and needlework, designing, painting, block printing, leather and metal work The success of the venture is indisputable

### INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 20TH 1926

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 189 (last week 312); scarlet fever 1644; diphtheria 1115; enteric fever 51; pneumonia 1142; puerperal fever 63, cerebro-spinal fever, 9; acute poliomyelitis 4; encephalitis lethargica 15; typhus fever 1; dysentery 5; ophthalmia neonatorum 105 No cases of cholera or plague were notified during the week

The case of typhus fever was notified from the county borough of Sunderland. Dr E Thorp, deputy medical officer of health for the borough, informs us that the source of infection has not yet been definitely ascertained The victim was a child of 3 years of age, and it is interesting to note that a woman in the same house died of pneumonia and meningitis a month previously, the crisis being on the twelfth day

*Deaths.*—In the aggregate of great towns including London there were 3 (0) deaths from enteric fever none from small pox 110 (36) from measles 12 (2) from scarlet fever 17 (1) from whooping-cough 19 (17) from diphtheria, 63 (22) from diarrhœa and enteritis under 2 years and 136 (10) from influenza. The figures in parentheses are those for London itself. The notified deaths from influenza are higher than in any previous week of the year

## A STATE MEDICAL SERVICE.

*To the Editor of* THE LANCET.

SIR,—A principal recommendation of the recent report of the Royal Commission on National Health Insurance was quoted in THE LANCET last week as follows: "The ultimate solution will lie, we think, in the direction of divorcing the medical service entirely from the insurance system, and recognising it, along with all the other public health activities, as a service to be supported from the general public funds." The view of the Commissioners will surprise those who have thought the question of nationalisation was moribund.

A fugitive interest was aroused in it, when within half an hour on a recent morning a youngish consultant and a retail chemist both expressed the opinion that State conduct of their respective professions must eventually come, and the sooner the better. I met the chemist again in the evening and found the imminence of a State service to be then appreciably less. Business was better, and a comparison of receipts as from Jan. 1st had revealed an unsuspected surplus of £47 over last year.

It has long been recognised as a weakness of democracy that whereas in theory the majority rule and order the manner of their existence, in practice compactly organised and sufficiently vocal minorities often impose their will upon the inarticulate mass. Ephemeral difficulties or even the personal embarrassments of the moment are not infrequently at the root of the unreflective advocacy of far-reaching social experiments which hold the promise of a material reward. This is an attitude we can readily understand and, up to a point, even sympathise with. To the majority of mankind material advancement is the most cherished good. But the public advocacy of a State Medical Service is never based upon grounds of self-interest, for social reformers are invariably altruists who live and move in a rarefied atmosphere of spirituality and are concerned only for the welfare of others. The private practice of a profession is quite properly categoried amongst the precarious livelihoods. Actually it is no more speculative than the conduct of a trading enterprise, where equally there must be a high percentage of failure or indifferent success. It is precisely the sporting or speculative character of a competitive undertaking which constitutes not a little of its lure for the energetic and capable; and the efficient speculator is never poor.

To function successfully a State service would require to substitute something for the competitive interest and the desire for realisation which spur the individual practitioner to greater effort. In short, it must contemplate the enrolment of idealists to whom the pursuit of knowledge and truth is in itself an end, and the reward of industry the consciousness of well-doing. The supply of genuine idealists being restricted, the service as constituted would presumably embrace a certain number of idealists together with a much larger number of scientists whose conception of the greatest good is a safe and pensionable £600, an eight-hour day, and a semi-detached suburban villa called "Chez Nous." The actual factor, however, which determines the advent or otherwise of a State Medical Service is economic. The proponents of such a service manifestly accept the perpetuation of inadequate industrial wages and low purchasing power, for in the presence of the reverse conditions it has no status. It is generally believed that commodity prices will become stabilised at about 140, a figure now reached, but wages, monetary and real, cannot remain at present levels if the country is to return to prosperity, as it unquestionably will. Both employers and the responsible Labour leaders recognise that under prevailing world conditions high wages are the [illegible]tant of high productivity, which alone enables manufactured articles to be sold at competitive prices. With the stabilisation of piece-work rates, the use of modern plant, and the removal of hampering trade-union restrictions the skilled mechanic within ten years will be earning £10 weekly and ordinary labour probably a pound a day. This will involve a considerable decrease rather than an increase of present State medical commitments.

History shows that periods of individualism regularly alternate with periods of socialism, each representing a reaction from extreme positions reached by the opposing humanistic theory. In 1920 many believed that a State Medical Service was at least within the bounds of possibility. This phase passed, leaving behind an unwelcome legacy of social services and salaried posts. We are now at the beginning of a period of intense and hopeful individualism.

I am, Sir, yours faithfully,
H. D. L. SPENCE.

Great Russell-street, W.C., March 29th, 1926.

## WHAT IS ORTHOPÆDIC SURGERY?

*To the Editor of* THE LANCET.

SIR,—A perusal of the February Transactions of the Orthopædic Section of the Royal Society of Medicine prompts me to ask through your columns the question: "What is orthopædic surgery?"

The cases shown in the Section included two of Charcot's disease, one of osteomalacia, and one of secondary ovarian sarcoma of the scapula, treated by inter-scapulo-thoracic amputation. The first three cases possess only a minor and incidental orthopædic interest and the last one, so far as I can see, none at all. We have travelled far from the time when orthopædic surgery was defined as the branch of surgery which deals with the deformities arising during the process of growth, and the subject still appears to be expanding indefinitely.

The recognition of a specialty in surgery is the result of an implied bargain, made in the public interest. On the one hand, the general surgeon acknowledges the superior knowledge of the specialist based upon long and exclusive devotion in hospital practice to his particular subject. The specialist on his side agrees to restrict his activities within the limits of his specialty. In cases such as those referred to I do not think orthopædic surgeons possess any special knowledge or experience. I doubt, in fact, whether their experience in such fields is equal to that of the general surgeon, and it appears to me that such cases should not be shown in a specialist Section of the Royal Society, but before the main Surgical Section, where they could be considered from a broad point of view, and in all their aspects.

When cases are shown publicly in a specialist Section, there is a clearly implied claim to superior skill and knowledge in their treatment. Cases in which this claim cannot be substantiated should be excluded. Alternatively, I think the Orthopædic Section should apply for absorption in the main Surgical Section of the Society.

I am, Sir, yours faithfully,
W. SAMPSON HANDLEY.

Harley-street, W., March 23rd, 1926.

## AN ESSAY IN EXPERIMENTAL EPIDEMIOLOGY.

*To the Editor of* THE LANCET.

SIR,—May I make one comment on the leading article which appears under the above heading in last week's issue of THE LANCET? In my first Milroy Lecture I said: "Many of the results which I wish to lay before you are . . . . the outcome of a joint investigation, for which Dr. Greenwood and I are equally responsible." If I may be allowed two other quotations from the same lecture, they will, I think, make clear the position as it appears to us both.

"It is not enough that the statistician should analyse the results obtained by the bacteriologist. He must take a full share in designing the experiments and in following their course."

"At the present moment, we believe that the best hope of elucidating the main questions at issue is to combine the experimental and statistical methods, by developing an experimental biometry of epidemic disease, in which the bacteriological and immunological factors shall not be so complex, and so little susceptible to control, as to defy analysis, while the numerical data shall not be so slight *as to preclude the application of statistical methods of inquiry.*"

Dr. M. Greenwood's share in the work is, of course, perfectly obvious from the context of the lectures, and I would not trouble you in the matter were it not that I have a very lively faith in the promises held out by a closer coöperation between the two methods of research. Team-work is not a magician's wand, potent to resolve all our troubles and perplexities; indeed, it can quite easily be overpraised and overdone. But from time to time occasions arise in which it becomes clear that successful attack on a particular problem requires the application of two technical methods, neither of which can be acquired easily or quickly, and which are not, in fact, at the disposal of a single individual; while two or more persons, possessing in their joint capacity a combination of technical experience which neither can command alone, may have a sufficient common stock of knowledge and ideas to see the same problem in much the same light. Under such circumstances team-work becomes natural, and therefore easy and profitable. There is, I think, little doubt that the study of epidemic disease offers one such occasion to the bacteriologist and the biometrician. I shrewdly suspect that many of the problems of infection and immunity, not usually included in the domain of epidemiology, would yield to attack along similar lines.

I am, Sir, *yours faithfully,*

Manchester, March 20th, 1926. W. W. C. TOPLEY.

next door, and would be able to enlarge their special departments in the near future.

Experience gained in maternity and child welfare work and the reduction of deaths from infantile diarrhœa clearly show that most benefit accrues where facilities for knowledge and treatment are easily available, and although it may not be possible to increase the number of venereal disease clinics at the present time, it is surely a retrograde policy to close any of them. The scheme of six large all-day clinics will, I fear, prove both more expensive and less efficient.

I am, Sir, yours faithfully,

STELLA CHURCHILL.

Chiswick, W., March 23rd, 1926.

direct loss to him, either in money or in time. This loss should be made up by a small grant from the mother hospital.

Your readers are more competent to appreciate or to criticise these observations than I am, being a layman. But all of us, medical or lay, who regard our hospitals as the places where disease is to be searched out and fought, must welcome any suggestion which is intended to increase the hospital's power as a fighting force, and is intended to ensure that all hospital men, whether their duties lie within or without the hospital walls, shall always be members of that force. Now, when a man leaves the hospital in which he has worked for years as student and houseman, the sting of the "Good-bye" is that he feels he is dropping out and has no further part in the great adventure.—I am, Sir, yours faithfully,

E. W. MORRIS,
House Governor.

London Hospital, Whitechapel, E., March 26th, 1926.

## A COMPENSATION PROBLEM.

*To the Editor of* THE LANCET.

SIR,—The following sequence of events in a male patient, aged 57, is of some interest.

The patient, X. Y. Z., sustained an accident to his back at the steel works by falling off a large mould on to the edge of a stage. There was much bruising to the muscles of the lumbar region, but no fracture or internal injury could be found. Four weeks later he complained of pain in the left groin and on examination a testicular tumour was found. This was removed 18 months after and found to be a rare tumour of the left testis of early malignancy. Four days after removal of the testis the patient complained of pain in the right iliac fossa and other symptoms of appendicitis. He was removed to hospital and the appendix was found inflamed with an early abscess forming. He made an uneventful recovery.

In view of the possible claim for compensation that may be made in this case I should be glad to hear any views of your readers on the possibility of either the testicular tumour or the inflamed appendix having developed as a sequel of the accident.

I am, Sir, yours faithfully,

March 23rd, 1926. PRACTITIONER.

# The Services.

### ROYAL ARMY MEDICAL CORPS.

Lt.-Cols. P. H. Falkner and S. M. A. Curran retire on retd. pay.

Maj. and Bt. Lt.-Col. J. A. Anderson retires on retd. pay and is granted the rank of Lt.-Col.

### ARMY RESERVE OF OFFICERS.

Lt.-Col. C. Clarke to be Maj. whilst empld. under Art. 505 (*b*), Royal Warrant for Pay and Promotion, 1922, and relinquishes the rank of Lt.-Col.

### TERRITORIAL ARMY.

Capt. S. McNaughton resigns his commn. and retains his rank.

Lt. P. Hickey to be Capt.

Capt. H. V. Forster (late R.A.M.C.) to be Lt. and relinquishes the rank of Capt.

### ROYAL AIR FORCE.

Flying Officer R. L. C. Fisher is granted a permanent commission in this rank.

M. J. Marren is granted a short service commission as a Flying Officer, for three years on the active list.

ST. MARY'S HOSPITAL POUND DAY.—As a result of the first Pound Day organised for the benefit of this hospital, which was held on March 18th, the sum of £600 was realised in money, and the groceries contributed amounted to more than a

# Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON: ELECTION OF PRESIDENT.—An extraordinary Comitia of the College was held on Monday, March 29th, at 5 P.M., the President, Sir Humphry Rolleston, Bart., being in the chair. The President delivered the annual address, much abbreviated in delivery because of the large amount of business before the Comitia. Reference was made to the changes made during the past year in the examination for the membership. Brief obituary appreciations were read of the nine Fellows who had died during the year, including Dr. Howard Tooth, Sir Richard Douglas Powell, Dr. Edward G. Browne, Dr. J. W. Russell, and Dr. G. H. Hunt.

A vote of thanks to the retiring President having been moved and carried, the College proceeded to the election of President. At the first ballot Sir John Rose Bradford received 51 votes, Lord Dawson 37, Sir William Hale-White 19, Dr. Raymond Crawfurd 14, and Dr. John Fawcett 11. The first two of these names were then submitted to a further ballot, when Sir John Rose Bradford received 81 votes and Lord Dawson 65. Sir John Rose Bradford was then inducted to the President's chair.

Dr. R. O. Moon was elected Assistant Registrar, having been nominated by the President at the last meeting of the Comitia, and Dr. J. Walter Carr was elected a representative of the College on the "Professional Classes Aid Council" in place of Dr. Newton Pitt, retired.

In reply to a letter received from the Royal Society, asking the College to appoint a representative to attend a meeting in the Society's rooms on April 30th, for the purpose of organising a celebration of the centenary of the birth of Lord Lister (April 5th, 1927), the President was appointed to represent the College.

Diplomas were granted in tropical medicine to 27 candidates.

Lord Dawson drew attention to the discontinuance of the publication of "Medical Science Abstracts and Reviews." The College affirmed its appreciation of the value of this publication, and hope was expressed that the Medical Research Council would resume it.

UNIVERSITY OF LIVERPOOL.—At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR DEGREES OF M.B. AND CH.B.

*Part I.*—T. Blezard, H. C. Calvey, F. R. Craddock, L. de Jongh, Lilian W. Edwards, E. E. Glenton, L. S. Goldman, A. W. Green, H. E. Hughes-Davies, Edna Morris, T. C. Newman; Muriel S. Roberts, J. B. Rushton, E. F. Thompson, J. L. Walker, A. J. Walsh, and Joan Watkins.

*Part II.*—L. de Jongh, T. Lotter, Ivy H. Rowlands, and J. L. A. Webster.

DIPLOMA IN TROPICAL MEDICINE.

W. J. Aitken, A. Ashworth, R. N. Bansikar; N. Bligh-Peacock, Effie G. Bolton, E. H. Boodrie, M. A. B. Brito-Mutunayagam, T. Cullen, H. N. Davies, B. G. V. Dias, E. G. A. Don, H. P. Fowler, Isabella J. Fowler, Katharine M. Hodgkinson, R. Jackson, K. H. Kamakaka, D. Lennox; A. W. Lewis, A. G. Mackay, N. McLean, M. MacSweeney, S. B. Malik, M. E. Merchant, E. F. Molony, S. G. Nashikkar, F. Oppenheimer, F. S. Paterson, L. D. Quigley, M. Rodrigues, A. S. Sachdev, B. Singh, J. Singh, S. A. Talib, C. L. Tan, Catharine F. Taylor, N. S. Turnbull, B. K. Vardya, and T. N. Varma.

DIPLOMA IN TROPICAL HYGIENE.

G. Clark, Ivy Collier, B. L. Davis, A. J. Hawe, D. M. Mackay, and D. A. Skan.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

J. H. Barrett, R. Hermon, J. M. Hosey, Irene E. Kenworthy, H. McE. Morris, and D. Ramage.

UNIVERSITY OF EDINBURGH.—At the Graduation Ceremonial recently the following degrees were conferred:—

DOCTOR OF SCIENCE.

Ronald Gray Gordon, M.D.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Roderick Macdonald.

It is announced that at the bicentenary celebrations of the Faculty of Medicine in June the degree of Doctor of Laws will be conferred on the following: Dr. A. Balfour, Director of the London School of Hygiene and Tropical Medicine; Dr. R. Howden, Professor of Anatomy, University of Durham; Sir George Newman, Chief Medical Officer of the Ministry of Health; Mr. Alexander Primrose, Professor of Clinical Surgery, University of Toronto; Sir John Robertson, Professor of Public Health, University of Birmingham; Dr. Ralph Stockman, Professor of Materia Medica and Therapeutics, University of Glasgow; Mr. A. L. Turner, President of the Royal College of Surgeons, Edinburgh; Sir Norman Walker, formerly Senior Lecturer on Diseases of the Skin, Edinburgh; and Mr. J. T. Wilson, Professor of Anatomy, University of Cambridge.

University of Durham.—In examinations held recently the following candidates satisfied the examiners:—

*Third M.B.—Pathology and Bacteriology, Materia Medica, Pharmacology and Pharmacy, Public Health, and Medical Jurisprudence.*—Samuel Carnotsky, Clarence D. C. Golding, Satyen Mozumder, Robert W. Rutherford, and Thomas A. W. Wilson.

University of Oxford.—Robert James Brocklehurst, B.M., University College and St. Bartholomew's Hospital, has been elected to a Radcliffe Travelling Fellowship of £300 for two years. Bernard Thomas Squires, student of medicine, University College, has been elected to a Christopher Welch Research Scholarship of £100 for four years.

Royal Institution.—The after-Easter lectures at the Royal Institution will begin on Tuesday, April 13th, at 5.15 P.M., when Prof. J. Barcroft will deliver a lecture on the Salivary Glands, which will be the first of four lectures by him on Organs of Multiple Function.

London University: Bloomsbury Site.—In a letter to the Treasury dated March 24th, 1926, the Vice-Chancellor of the University expresses the Senate's hope that the Treasury will still take such steps as are now practicable to secure the retention of as large a part as possible of the Bloomsbury site for University purposes, and announces the appointment of a deputation to confer with the Government on the general situation This deputation consists of the official members, Sir William Beveridge, Sir William Collins, Prof. Filon, Dr. Graham Little, Sir Josiah Stamp, and Sir Holburt Waring.

National Association for the Prevention of Tuberculosis.—The twelfth annual conference is to be held at Glasgow from July 1st to 3rd. Discussions will deal with the Provision for the Care of Non-Pulmonary Forms of Tuberculosis (opened by Dr. A. S. M. Macgregor and Mr. James Taylor), and the Actual Place and Function of the Tuberculosis Dispensary in the Tuberculosis Scheme (Sir Robert Philip and Dr. Lissant Cox). There will also be communications dealing with recent advances in tuberculosis by a number of authorities, and institutions in the neighbourhood will be visited. The conference is open to all persons interested in tuberculosis on paying a fee of one guinea. Particulars of reduced railway fares and the like may be had from the secretary at 20, Hanover-square, London, W. 1.

Balneological Congress at Aix-la-Chapelle.—The forty-first congress of the German Balneological Society is being held this year at Bad Aachen (Aix-la-Chapelle) from Tuesday, April 6th, to Sunday, April 11th, under the presidency of Prof. Dietrich. Wednesday opens with an introductory address by Prof. H. Strauss, of Berlin, on the Origin and Differential Diagnosis of Chronic Arthritis, and the forenoons of that and the next three days will be occupied by the reading of more than 60 papers dealing with many aspects of gout, rheumatism, and fibrositis, and the effect of various baths on these and other systemic affections. Demonstrations of various kinds will be given in the afternoons by local balneologists and members of the society from Wiesbaden, Nauheim, Pistany, Wildbad, Marienbad, and other continental spas. Saturday afternoon and Sunday will be given up to excursions in the Rhineland. Information may be obtained from Dr. Max Hirsch, Berlin-Charlottenburg, Fraunhofer Strasse 16.

Fellowship of Medicine and Post-Graduate Medical Association.—On Thursday, April 15th, at 3 P.M., Mr. W. E. Tanner will give a demonstration in clinical surgery at the Prince of Wales's General Hospital, Tottenham. This demonstration will be free to members and to general course ticket holders of the Fellowship.—From April 19th to May 1st the Bolingbroke Hospital, Wandsworth Common, will hold an intensive course in medicine, surgery, and the specialities.—During May there will be two courses lasting the entire month—on Psychological Medicine at the Maudsley Hospital, Denmark Hill, and on Venereal Diseases at the London Lock Hospital. This latter hospital will hold the clinical course irrespective of numbers, but the lectures will only be given if there is a minimum entry of eight.—From May 3rd to 22nd there will be a clinical and an operative course at the Central London Throat, Nose and Ear Hospital.—The Royal Waterloo Hospital will hold a course in medicine, surgery, and gynæcology from May 3rd to 22nd, with opportunities for attendance in the departments of the hospital.—From May 3rd to 15th the Infants Hospital will hold an afternoon course under the direction of Dr. Eric Pritchard, and a three weeks' course in ophthalmology will be given by the Royal Westminster Ophthalmic Hospital from May 3rd to 22nd.—Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Manchester Poor-law Patients. — The Manchester Board of Guardians have approved of a scheme whereby the Poor-law sick patients will receive the same treatment as panel patients. Hitherto Manchester Poor-law doctors have had to provide the medicine for the patients. The new arrangement provides for all prescriptions to be made up by the chemists.

College of Nursing.—From Thursday, April 8th to 15th, there is to be a post-graduate course at the College, arranged by the Public Health Section. Amongst those who will give lectures are Dr. Eric Pritchard, Dr. Letitia Fairfield, Sir Henry Gauvain, Sir John Robertson, Dr. W. F. Whitley, Mr. Sampson Handley, Dr. C. P. Symonds, Dr. James Wheatley, Prof. Louise McIlroy, and Dr. Margaret Rorke. Particulars may be had from Miss Hester Viney, College of Nursing, Henrietta-street, London, W. 1.

Messrs. J. and A. Churchill expect shortly to publish "The Chemistry of the Proteins," by Dr. Dorothy Jordan Lloyd; "Recent Advances in Biochemistry," by Dr. John Pryde; the fourth edition of Sir Maurice Craig's "Psychological Medicine," in which Dr. Thomas Beaton has collaborated; the second edition of Dr. M. Dobbie's translation of Arvedson's "Medical Gymnastics and Massage in General Practice"; and a small book called "Ophthalmic Nursing," by Mr. Maurice Whiting.

Training and Appointment of Health Visitors. Ministry of Health Circular 680 (H.M. Stationery Office, 1*d.*) contains the information that the Minister has approved the Royal Sanitary Institute as the central examining body to conduct examinations for health visitors and to issue health visitors' certificates. On and after April 1st, 1928, the Minister will not approve the appointment of a woman for the first time as a whole-time officer of a local authority with health visiting duties unless she has obtained this certificate, or the diploma issued to students who, before April 1st, 1925, began an approved course of training under the regulations of 1919. The position of existing health visitors is safeguarded, but it is considered desirable that women who have given at least five years' satisfactory service as whole-time health visitors should endeavour to obtain the new certificate. As from Jan. 1st, 1928, the approval given by the Local Government Board under the Health Visitors (London) Order, 1909, to the certificates for health visitors of the Royal Sanitary Institute, the Royal Institute of Public Health, the National Health Society, and the Battersea Polytechnic is withdrawn.

Cremation Society of England.—The annual meeting of this society was held at 12, Stratford-place, London, W., on March 24th, when Dr. P. Chalmers Mitchell, Chairman of the Council, presided. On the adoption of the report, the Chairman expressed gratification at the progress made during 1925. The number of cremations in Great Britain had increased, especially in the London area. With the existing cry for building sites, playing fields, and open spaces, he said it was extraordinary that it was not more fully realised how much space was needlessly wasted in cemeteries. Cemeteries were expensive to keep up and invariably showed a loss, whereas crematoria showed a profit, and would show more profit if developed on a larger scale. The number of cremations at the 16 British crematoria during the year was 2701, showing an increase of 800 as compared with the figures of 1924. Of the total for 1925, 1533 cremations were carried out at the four crematoria in Greater London—viz., Golders Green, Ilford, Norwood, and Hendon Park. The Duke of Bedford was re-elected President of the society.

A Visit to Czecho-Slovakia.—As already announced the International Society of Medical Hydrology is this year holding its annual meeting in Czecho-Slovakia from April 15th to 22nd, and has issued an invitation to members of the medical profession to join in the conference and tour which have been arranged. The places to be visited are Karlsbad, Marienbad, Franzensbad, Prague, Pistany, and the spas of the Tatra mountains, and the society and its friends will be the guests of the Czecho-Slovakian Government and of the spa municipalities during their seven days' stay in Czecho-Slovakia. The arrangements include an official reception at Prague on April 19th, and a special conference on rheumatism at Pistany, in which Sir William Willcox (London), Dr. Kahlmeter (Stockholm), Dr. van Breemen (Amsterdam), Prof. A. Strasser (Vienna), Prof. M. Netousek (Bratislava), Dr. Baltaceanu (Budapest), and others will take part. A limited number of applications to join the tour can still be entertained. They must reach the hon. secretary, at 30, Devonshire-place, London, W. 1, at latest by the first post on Monday, April 5th. The total expenses of the visit, including fares to Czecho-Slovakia at special rates, are estimated at about £15. Visitors from England will leave London on Wednesday, April 14th, at 9.15 A.M.

**Royal Sanitary Institute.**—A sessional meeting will be held in the Town Hall, Weston-super-Mare, on Friday, April 9th, at 11 A.M., when there will be a discussion on the Rôle of Different Agencies in the Improvement of the Milk Supply. Amongst those who will take part will be the hon. local secretary, Dr. W. G. Savage. Those who intend to be there should notify him at the County Health Department, Boulevard, Weston-super-Mare, not later than April 5th.

**The late Prof. Jonnesco.**—Prof. Thomas Jonnesco, who died on March 28th at Bucharest at the age of 66, was well known in this country and elsewhere for his work on the excision of the cervical sympathetic. He studied in Paris and was at one time prosector in the Faculty of Medicine, returning later to Bucharest as professor. He was a brother of the late Mr. Take Jonnesco.

**Optical Dispensing.**—A deputation from the Joint Council of Qualified Opticians and the British Optical Association was received by the Minister of Health on March 26th and discussed with him the Bill to secure the registration of optical practitioners and to regulate the practice of Sight Testing and Optical Dispensing, which has been presented to Parliament by a private Member. Mr. Neville Chamberlain admitted that the opticians had a case up to a certain point. He had some sympathy with their claim that persons who had properly qualified themselves to treat errors of refraction not requiring medical attention should have a special label, and he would like to meet this point. The difficulty out of which he could not see his way was how patients suffering from simple errors of refraction could be distinguished from those in whom defect of vision was due to some pathological condition.

## NOTES ON CURRENT TOPICS.

### Births and Deaths Registration Bill.

The Bill introduced by Mr. Tinne to amend the law relating to the registration of births and deaths was considered on Tuesday, March 23rd, by a Standing Committee of the House of Commons. The object of this Bill is to render more complete the legal safeguards in relation to the disposal of the dead. so as to prevent any possibility of the concealment of crime. Local authorities are empowered by the measure to arrange for the medical inspection in certain instances of the bodies of deceased persons. and stillbirths are required to be registered as an additional safeguard for the protection of infant life. Clause 1, which prohibits the disposal of a body except on a registrar's certificate or a coroner's order, was agreed to with slight amendments, as were also a number of other clauses containing provisions of a consequential character. Major-General Sir Richard Luce moved an amendment providing that if the cause of death was unknown to the medical practitioner called upon to certify, or if he was of opinion that death had arisen from, or been accelerated by any violence, neglect, poison, or other unnatural cause, or had followed as an immediate sequence to the administration of an anæsthetic, he should not grant any certificate of death, but should forthwith report the circumstances to the coroner. He said that the object of the amendment was to lay down some definite procedure to guide medical practitioners who might be in doubt. Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health) said that there was no necessity for the amendment because it was already the duty of medical men and others under the Common Law in cases of this kind to give immediate notice to the coroner. Sir Richard Luce withdrew his amendment.

The same Bill was further considered in Standing Committee on Thursday, March 25th. Mr. Groves opposed Clause 7, which empowers certain local authorities in cases where a body has not been seen by a registered practitioner since the death to provide for its medical inspection on the request of the coroner for the district. He said there was a fear among a large section of the population that insufficient attention was paid by the medical profession to the possibility of premature burial. Sir Kingsley Wood supported the clause. Referring to a proposed new clause standing in the name of Mr. Groves which provided that a death should not be registered unless and until there had been delivered to the registrar for the district a medical certificate of the fact and cause of death, he said this was a proposal which had wrecked every previous Bill of this kind. In the view of the Government there was not a sufficient body of evidence to warrant such a drastic provision. On a division the clause was struck out of the Bill by 10 votes to 7. Mr. Groves did not move his proposed new clause. The Committee stage was concluded and the Bill was ordered to be reported with amendments to the House.

## HOUSE OF LORDS.

### Thursday, March 25th.

### Legitimacy Bill.

The Lord Chancellor moved the second reading of the Legitimacy Bill which he said was in substance similar to the Bills of 1924 and 1925. The main purpose was contained in the first clause which provided that where the parents of an illegitimate person married, or had married one another, the marriage should render that person legitimate from the commencement of the Act if the marriage had already taken place, or from the date of the marriage, whichever last happened. The schedule of the Bill provided that the Registrar-General should not re-register the birth of a legitimated person in any case where information with a view to obtaining such re-registration was not furnished to him by both parents, with three exceptions. The first was that the person acknowledging himself to be the father of the legitimated person had been entered in the register in pursuance of Section 7 of the Births and Deaths Registration Act, 1874; the second, that the paternity of the legitimated person had been established by an affiliation order, or otherwise. by a court of competent jurisdiction; and third, that a declaration of legitimacy had been made under the Legitimacy Declaration Act, 1858.

Viscount Haldane said that on the whole the Bill was a fair compromise on a matter in regard to which there had been a great divergence of opinion.

The Bill was read a second time.

### Coroners Bill.

The Coroners (Amendment) Bill was considered on report.

The Lord Chancellor moved a new clause providing that the Coroners Act, 1892 (which relates to the appointment and powers of deputy coroners) should apply with the necessary modifications to the coroner for the King's household as it applied to county and borough coroners, and in particular with the modification that the appointment of a deputy to the coroner for the King's household should be subject to the approval of the Lord Steward. He explained that it was necessary to make provision for the appointment of a deputy coroner of the King's household in case the principal coroner should be unable to perform his duties.

The new clause was agreed to.

On Clause 21, which deals with the power of a coroner to request specially qualified persons to make post-mortem and special examinations, Subsections (2) and (3) as printed in the Bill were omitted on the motion of the Lord Chancellor, and the following new subsections were inserted in their place:—

(2) If any person who has made such a post-mortem or special examination as aforesaid is summoned by the coroner as a witness he may be asked to give evidence as to his opinion upon any matter arising out of the examination, and as to how in his opinion the deceased came by his death.

(3) The provisions of this Act prescribing the fees payable to medical witnesses shall not apply with respect to any examination made at the request of the coroner under this section. but the fees payable in respect of any such examination shall be such as may be prescribed by the schedule of fees, allowances, and disbursements made by a local authority under Section 25 of the Coroners Act, 1887, or by rules made by the Secretary of State under this Act.

The Lord Chancellor moved the following new clause dealing with fees to medical witnesses:—

The fees payable to a legally qualified medical practitioner who has made any post-mortem examination by the direction or at the request of a coroner, or who has attended an inquest in obedience to a summons of a coroner under the Coroners Act, 1887, shall (save as in this Act otherwise expressly provided) be as follows, that is to say: (*a*) For attending to give evidence at any inquest whereat no post-mortem examination has been made by the practitioner, one guinea; and (*b*) for making a post-mortem examination of the body of the deceased and reporting the result thereof to the coroner without attending to give evidence at an inquest, one and a half guineas; and (*c*) for making a post-mortem examination of the body of the deceased (including the making of a report, if any, of the result thereof to the coroner) and for attending to give evidence at an inquest on the body, two guineas:

Provided that no fee or remuneration shall be paid to a medical practitioner for the purpose of a post-mortem examination instituted without the previous direction or request of the coroner.

The new clause was agreed to.

On the motion of the Lord Chancellor the following new clause was agreed to applying the Coroners Acts to the City of London:—

From and after the occurrence of the next vacancy in the office of coroner for the City of London the provisions of this Act and of any other enactment relating to the office of borough coroner or to borough coroners shall apply with respect to the City of London as if the Common Council were the local authority and as if the coroner for the City of London were a borough coroner, and any expenses of the Common Council under the said enactments shall be defrayed out of the general rate.

The report stage of the Bill was concluded.

# HOUSE OF COMMONS

## WEDNESDAY, MARCH 24TH.

### *The Geneva Opium Convention*

Viscount SANDON asked the Secretary of State for Foreign Affairs whether the Opium Convention had been ratified by the Government; if not, why it had been delayed and when it would be ratified; what Governments had deposited ratifications at the League of Nations; whether the Convention had yet taken effect; and whether the Central Board had been set up.—Sir A. CHAMBERLAIN replied: The British ratifications of the Opium Agreement and Dangerous Drugs Convention, signed at Geneva on Feb. 11th and 19th, 1925, respectively, were deposited with the League of Nations on Feb. 17th. So far as H.M. Government are aware, no foreign Power has yet ratified the Agreement or Convention. Under Article 36 of the Convention, the Convention will not come into force until it has been ratified by ten Powers and under Article 19 the Central Board will be appointed within three months from the coming into force of the Convention. Under Article 14 of the Opium Agreement, the Agreement will come into force on the ninetieth day after the receipt by the Secretariat General of the League of Nations of ratifications by two Powers.

## THURSDAY, MARCH 25TH.

### *Physical and Medical Standards in the Navy*

Mr. HORE BELISHA asked the First Lord of the Admiralty why the physical and medical standard of the non-continuous service recruits was being lowered, seeing that present serving ratings who had previously passed the highest physical and medical tests were now being invalided in large numbers, the cause in the majority of cases not being attributable to naval service.—Mr. DAVIDSON (Parliamentary Secretary to the Admiralty) replied: Assuming that the question refers to the physical and medical standards for special service seamen, it is not considered necessary to insist on quite the same high physical and medical standards for special service seamen as for long service ratings. The proportion of naval ratings who are invalided annually is quite small.

### *Resignation of Medical Staff at Paris Hospital.*

Major-General Sir RICHARD LUCE asked the Secretary of State for Foreign Affairs whether his attention had been called to the position created at the Hertford British Hospital, Paris, by the resignation of the medical staff; and, if so, what action he proposed to take in the matter.—Mr. A. M. SAMUEL (Parliamentary Secretary to the Department of Overseas Trade) replied: I am aware that the medical staff of the Hertford British Hospital, Paris, resigned in November, 1924. The staff has been replaced, and no action on the part of H.M. Government appears to be necessary.

### *Accident to Boys at Coal mines.*

Mr. HAYDAY asked the Secretary for Mines the number of accidents, fatal and non fatal, respectively, received by boys of 16 years of age and under employed in or about the coal mines for the year ending 1925.—Colonel LANE FOX replied: Seventy nine boys of 16 years of age and under employed in and about mines under the Coal Mines Act were killed during the year 1925, and 15,211 were disabled for more than three days. The number of boys employed in 1924, the latest year for which figures are available, was 41,700.

### *Artificial Sunlight Treatment*

Sir HARRY BRITTAIN asked the Minister of Health to what extent the artificial sunlight treatment had been introduced into the hospitals in this country; and whether this form of treatment was proving successful.—Mr. N. CHAMBERLAIN replied: I have no complete information as to the number of hospitals in this country in which this form of treatment is provided, but arrangements for the provision of this treatment have been approved in connexion with tuberculosis and maternity and child welfare schemes, in the case of 26 hospitals and sanatoria (exclusive of tuberculosis dispensaries and maternity and child welfare clinics). Reports on the approved schemes are now being considered in my department and I am not yet in a position to give a complete reply to the second part of the question, but I may say that this form of treatment, if appropriately applied, is undoubtedly beneficial in many cases.

### *Approved Societies and Dental Treatment*

Mr. ROBINSON asked the Minister of Health what approved societies made provision for dental treatment; and if he would take steps to ensure that dental treatment and the provision of dentures should be included in the treatment provided under the National Health Insurance Acts.—Mr. NEVILLE CHAMBERLAIN replied: Some 3500 approved societies and branches in England, having a total membership of over 10,500,000 insured persons have adopted schemes of additional benefits that include payments towards the cost of dental treatment. These numbers are likely to be materially increased from next July, when schemes following the second valuation will become operative for societies and branches valued as at the end of 1923. The Royal Commission on National Health Insurance, who considered the subject exhaustively, came to the conclusion that while a complete dental service for the whole insured population would be eminently desirable, it is not at present financially practicable, and they recommended that the general arrangements for dental service under additional benefit schemes should be continued. Societies and branches having a sufficient disposable surplus on valuation are reminded of the possibility of their adopting dental benefit as an additional benefit, and I propose that this shall remain the practice.

### *Encephalitis Lethargica*

Mr. BRIANT asked the Minister of Health the number of cases of encephalitis lethargica notified during each of the years 1922, 1923, 1924, and 1925.—Mr. N. CHAMBERLAIN replied: The information asked for is as follows: Number of cases notified in England and Wales (including port sanitary districts): 1922, 454; 1923, 1025; 1924, 5039; 1925, 2035 (provisional).

### *Reductions in Pensions Staff*

Lieut. Colonel DALRYMPLE WHITE asked the Minister of Pensions what reduction of staff was effected in the Ministry of Pensions during the year 1925, and what were the respective percentages of reduction in Scotland and in the rest of the country.—Major G. C. TRYON replied: The staff of the Ministry were reduced, during 1925, by 4356, from 16 475 to 12 110, the percentage reduction in Scotland being 23·5 and in the rest of the country 26·7.

## FRIDAY, MARCH 26TH.

### FACTORY LAW REFORM.

Miss WILKINSON moved the second reading of the Factories Bill, a measure introduced by the Labour Party to consolidate with amendments the various enactments relating to factories and containing 113 clauses dealing with health, safety and welfare conditions, accidents and industrial diseases and the employment of women, young persons, and children. She said that during the last 25 years there had been an extraordinary increase in accidents in factories and workshops. The number in 1924 was 159,723 involving actual absence from work, or an increase compared with 1923 of 11,000. There were in 1924 950 fatal accidents, an increase of 89 over 1923. The Chief Inspector of Factories had pointed out that all accidents were not recorded. The Industrial Fatigue Board, in their report for 1925, said the loss of time due to sickness, most of it preventable, cost the country ten times more than strikes and labour disputes. To prevent this waste of human assets and human capital was the object of the Bill. This was a private Member's Bill only in a technical sense. It was drawn up by the Home Office originally. She believed its godfather was Mr. Bridgeman, the present First Lord of the Admiralty, but his work had been extended and considerably improved by Mr. Arthur Henderson when he, too, was Home Secretary. The Bill was, in fact, founded upon numerous inquiries, conferences, and special reports. It contained a very elaborate health code, dealing with cleanliness, overcrowding—increasing the space for each worker from 250 to 400 cubic feet—temperature, ventilation, lighting, sanitary conveniences, and also general provisions for safety. The employment of children was prohibited. For women and young persons the total hours to be worked, exclusive of intervals for meals and rest, were not to exceed nine in any day or 48 in any week, and certificates of fitness of young persons for employment would have to be provided. The new clauses and the altered clauses provided health and safety codes and a general improvement in factory law. There was not one thing in the Bill which good employers were not doing already.

Mr. STAMFORD seconded the motion for the second reading.

Captain MACMILLAN moved the following amendment:

> "That this House, while recognising the necessity for the introduction during this session of a Bill to consolidate and amend the laws relating to factories for the purpose of circulation and discussion in consultation with the interests affected, is of opinion that a measure of such far reaching importance should not be introduced as a private Member's Bill."

He said that the procedure contemplated in his amendment was that the Government should introduce a Bill dealing with this subject this session for the purpose of circulation and discussion by all the interests affected. As a result of this method he hoped that by the time the Bill put forward by the Home Secretary went to Committee it might be to all intents and purposes an agreed measure. They looked to the Government to produce a fair-minded Bill which would not be calculated to throw unreasonable demands on industry and which would confer continuous and progressive benefits on those engaged in industry.

Sir Leslie Scott seconded the amendment.

Sir W. Joynson-Hicks (Home Secretary) said while he was keen on all questions of social reform, and the Factories Bill was one of the first measures which he took in hand at the Home Office, nothing was to be gained by exaggerating the evils of the present system. It was untrue to say that if the Bill were not passed this year thousands of lives would be lost by accidents in the factories. There had been a slight increase in the number of fatal accidents recorded during the past year, but the numbers had persistently risen and fallen in proportion to the number of men and women employed in trade. In 1913 the number was 1309, and in 1919, when more people were employed, it was 1385; and in 1920, when trade was at its highest point, 1404. While he had been considering the Factories Bill improvements in nine or ten considerable industries had been made by regulations issued by the Home Office and arrived at with the concurrence of the employers and workers concerned. The Bill now presented for second reading conferred great powers and responsibilities on the Home Secretary, and in drafting his own Bill he had been doing his utmost to relieve the Home Office of such powers. As nineteen-twentieths of Mr. Bridgeman's Bill was contained in the Labour Government's Bill, so nineteen-twentieths of both these Bills would be contained in the forthcoming Factories Bill. He did not, however, propose to include the provisions affecting night baking. His Bill would abolish the distinction between textile and non-textile factories, and between factories and workshops. He had included new provisions affecting cleanliness, overcrowding, temperature in factories, and sanitary conveniences. There would be special medical provision and supervision in classes or descriptions of factories where there was exceptional liability to sickness or disease; and welfare provision with regard to drinking water, first-aid outfits for workers, protective clothing, and so forth. Many special health provisions included protection against dust, against the lifting of weights, and also dealt with underground work. There was a good deal to be said in regard to the terrible hours worked by women in a few industries. He hoped to deal with that apart from the Washington Convention. He was authorised by the Prime Minister and the Cabinet to say that he would introduce a Factories Bill during the current session for the purpose of consideration and discussion at the earliest possible moment in the session of 1927. That Bill would be one of the principal Government measures of next year and they would do their utmost to pass it into law.

After further discussion the amendment was carried by 184 votes to 109—majority 75.

## Appointments.

Evans, W., M.B., B.S. Lond., has been appointed Assistant Pathologist to the London Hospital.

Gilchrist, Susan, M.B., Ch.B. Liverp., Assistant Medical Officer of Health, Hull.

Holmes, A. Hillyard, M.D. Manch., M.R.C.P. Lond., Visiting Physician to Withington Institution and Hospitals, Manchester.

Hutchinson, R. J., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Haslemere District of the County of Surrey.

## Vacancies.

*For further information refer to the advertisemnt columns.*

*Alton, Hants, Lord Mayor Treloar Cripples' Hospital and College.* Second Asst. Res. M.O. £300.

*Belfast, Mater Infirmorum Hospital.*—Hon. Asst. Gynæcologist.

*Birmingham, Public Health Dept., Tuberc. Sect.*—Asst. M.O. £450.

*Brighton, Sussex Throat and Ear Hospital.*—Hon. Asst. S., Hon. Clin. Asst., and Hon. Asst. Anæsthetist.

*Cambridge, Addenbrooke's Hospital.*—Cas. O., and Res. Anæsthetist. At rate of £130.

*Carmarthen, Joint Counties Mental Hospital.*—Jun. Asst. M.O. £300.

*Derbyshire Royal Infirmary, Derby.*—H.S. £200. Also Asst. H.S. and Cas. O. Each at rate of £150.

*Exminster, Devon Mental Hospital.*—Jun. M.O. £300.

*Gloucester County Mental Hospitals, Wotton and Barnwood.*—Jun. Asst. M.O. £350.

*Hospital for Epilepsy and Paralysis, Maida Vale, W.*—Res. M.O. and H.P. At rate of £150 and £100 respectively.

*Lambeth Parish Hospital, Brook-street, Kennington, S.E.*—Jun. Asst. M.O. £200.

*London Temperance Hospital, Hampstead-road, N.W.*—Surg. Reg. 40 guineas.

*Macedonia Friends Council for International Service.*—Med. Man required. £14 monthly.

*Manchester Hospital.*—Res. Surg. O. £200

*Manchester Royal Infirmary.*—H.S. to Aural, Gynæcological, and Ophth. Depts. At rate of £50. Dickinson Pathology Scholarship. £75. Dickinson Research Travelling Scholarship. £300

*Metropolitan Hospital, Kingsland-road, E.*—Sen. H.P. and H.S., Jun. H.P. and H.S., and two Cas. O.'s. Each at rate of £100.

*Parish of St. John, Hampstead, New End Hospital.*—Sen. Res. Asst. M.O. £250.

*Prince of Wales's General Hospital, Tottenham, N.*—Two H.S.'s. and one H.P. At rate of £120. Also Jun. H.S. and Jun. H.P. At rate of £90.

*Royal Chest Hospital, City-road, E.C.*—Res. M.O. and H.P. At rate of £150 and £100 respectively.

*Royal National Orthopædic Hospital, 234, Great Portland-street, W.*—Hon. Ophth. S. and Hon. Dental S.

*Royal Northern Hospital, Holloway, N.*—H.P. and H.S. Each at rate of £70.

*St. Bartholomew's Hospital, E.C.*—Rose Research Fellowship in Lymphadenoma. £600.

*St. Mary's Hospital for Women and Children, Plaistow, E.*—Asst. Res. M.O. At rate of £130.

*Sunderland Borough Mental Hospital, Ryhope.*—Asst. Med. Supt. £500.

*Truro, Royal Cornwall Infirmary.*—H.S. £170.

*Walthamstow, Wanstead and Leyton Hospital, Orford-road, E.*—Jun. H.S.

*West Ham County Borough.*—Asst. M.O. £600.

*West London Hospital, Hammersmith-road, W.*—Hon. Med. Radiologist.

*West Middlesex Hospital, Isleworth.*—Asst. Med. Supt. £250.

*Westminster Hospital, Broad Sanctuary, Westminster, S.W.*—Asst. Dent. S.

*York City Mental Hospital, Fulford, York.*—Asst. M.O. £440.

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the Districts of the Uxbridge and Brentford County Courts (Circuits 34 and 46 respectively). Applications should reach the Private Secretary, Home Office, not later than April 21st.

## Births, Marriages, and Deaths.

### BIRTHS.

Grantham-Hill.—On March 19th, at Port Sudan, the wife of C. Grantham-Hill, M.B., of a son.

Hickinbotham.—On March 25th, at Colchester, the wife of J. R. Hickinbotham, M.B., of a daughter.

Martin.—On March 20th, at New Brook House, Atherton, Lancs, the wife of Major W. Y. Martin, T.D., R.A.M.C.T. of a daughter.

### MARRIAGES.

Parkes—Mackintosh.—On March 27th, at Withington Congregational Church, Manchester, Miles Parkes, M.B., Ch.B., to Annie Emily Mackintosh, M.B., Ch.B.

### DEATHS.

Finlayson.—On March 19th, very suddenly at his residence, Elson-road, Formby, Lancs, Harold Turner Finlayson, M.B., Ch.B., aged 36.

Yourdi.—On March 23rd, at Jersey Dispensary, Lieut.-Colonel John Robert Yourdi, O.B.E., R.A.M.C. (Retired List), of Roslyn, La Rocque, Jersey.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Child Welfare in Liverpool.—At the twentieth annual meeting of the Child Welfare Association, held in Liverpool on March 22nd, it was stated that at one time the Association had a warehouse where 250 spinal carriages were stored; now two dozen are sufficient for its needs. Throughout the length and breadth of Liverpool, said the chairman, it would be difficult to find a child growing up into a permanent cripple for lack of efficient treatment. During the year 4885 new applications for help were received, 32,000 parents advised and helped, 1770 children maintained in convalescent homes, 20,000 visits paid to the homes of the children, and 40,000 orders issued for milk for children. Last year a new wing was added to the hospital at Leasowe, and this with other developments cost £24,500.

Testimonial to Dr. Herbert Jones.—The Herefordshire Medical Society is organising a testimonial to Dr. Herbert Jones, medical officer of health for the Herefordshire combined districts, who has been obliged to resign his appointment on account of ill-health, largely due to services in the war. Dr. Jones has a distinguished record of service. In the words of the executive secretary of the Society of Medical Officers of Health, "he has been the chief mover in the matter of security of tenure and superannuation for medical men holding public appointments. In other matters also he has worked as hard for the British Medical Association as for this society, and he has been so busy looking after the interests of other people that in the opinion of many of his friends he has not been ready enough to fight for his own." Dr. Jones's work has been of service to the profession as a whole, and the Herefordshire Medical Society is accordingly making an appeal beyond the limits of the county. Subscriptions should be sent to Dr. John Steed, Staunton-on-Wye, Hereford, before April 30th.

# Notes, Comments, and Abstracts.

## HELIOTHERAPY, PHOTOTHERAPY, AND THE OPEN AIR.

AT a meeting of the Harveian Society on March 18th Dr. Gordon Pugh, chief medical officer of the Children's and Surgical Tuberculosis Services of the Metropolitan Asylums Board, made some interesting observations on prevailing ideas of light treatment. Heliotherapy and phototherapy, he said, were being widely described in the press as more or less recent discoveries of very great value. In particular stress was being laid on an increase in the bactericidal power of the blood, which was supposed to have important effects in the prevention and cure of disease. Dr. Leonard Hill, however, had said at Bath last September that a similar rise was produced by heat or a mustard poultice whenever these produced a lasting erythema. Some of the claims made appeared rather extravagant, and it had to be considered whether any really new therapeutic principle was being introduced, or whether in heliotherapy, and to a more limited extent in phototherapy, the old-established healing agents—fresh air and surface hyperæmia—were appearing in another, perhaps more convenient, form.

After recalling the totally inadequate provision for London's cases of surgical tuberculosis before the hospitals at Alton and Carshalton were opened in 1908 and 1909 respectively, Dr. Pugh related his impressions of the three methods of treatment as experienced at Carshalton—namely: (1) open-air therapy, which was British in origin, the first hospital for the complete open-air treatment of surgical tuberculosis being the Baschurch Hospital, founded by Miss Hunt in 1902; (2) heliotherapy, which might be called the Swiss method, since it owed its popularity to the efforts of Dr. Rollier, who began to use general sunlight baths in 1903; and (3) phototherapy, which might be regarded as Danish, as it was started in 1894 by Dr. Finsen, who died ten years later. Phototherapy had been made more generally available by Kromayer in 1901, when he introduced the mercury-vapour quartz lamp; and had been modified still further in 1913 by Reyn, who added to local treatment general irradiation by the carbon-arc lamp on the ground that its rays more nearly resembled those of the sunlight used by Rollier.

### *Heliotherapy and the Open Air.*

Speaking first of constitutional treatment by the open-air method, Dr. Pugh showed photographs of the satisfactory results obtained by this means at Carshalton in surgical tuberculosis, marasmus, and rickets, before the gradual adoption of heliotherapy from 1914 onwards. Each of the component parts of open-air life, he said, was of importance—the exposure of limited portions of the body to movements of air, changes of temperature, and sunshine or skyshine; the effect of breathing cool air with low vapour tension in promoting evaporation from the respiratory membrane, and so enhancing the outflow of secretion from it and the flow of lymph and arterial blood through it, and possibly other attributes yet unrecognised. In addition, there was the potent influence, whatever it might be, embraced in the term "change of air and environment."

Heliotherapy might be regarded as an improved form of open-air therapy, the presence of sunlight encouraging and rendering the open-air life more easy and pleasant. The main evidence for Rollier's belief that the sunlight was the important factor rather than the open air, was that the deeper the pigmentation became the better the prognosis. Rollier appeared to regard pigment as a transformer of light energy into energy which was spent in some chemical reaction useful in defence. It could not be denied, said Dr. Pugh, that a close parallelism between pigmentation and favourable prognosis—if such parallelism really existed—would be very strong evidence that the sunlight was the potent agent; but Dr. Pugh's observations at Carshalton did not confirm it. In 1922 a careful note was made of the pigmentation of 232 cases of tuberculosis of spine, hip, and knee, many of them severe cases admitted with sinuses. Three and a half years afterwards, when all except 21 nearly convalescent cases were either cured or dead, they were classified according to result. The mortality among the "very good" pigmenters had been 16 per cent., the "good" pigmenters 15 per cent., the "slight" pigmenters 10 per cent., and the non-pigmenters 0 per cent. He regarded this as disproving Rollier's theory. Dr. Hill, he thought, had reached the solution when, in 1922, after an investigation in collaboration with Dr. Argyll Campbell, he attributed the benefit of heliotherapy as conducted at Alton mainly to the great rise in metabolism which occurred as a result of the cooling power of the open air, and added that the rise due to sunlight per se was insignificant, but that sunshine promoted evaporation from, and flow of lymph through, ulcers and discharging sinuses, *and also warmed the diseased parts exposed to it.*

It was true that Dr. Hill had modified his views since then, but so far Dr. Pugh had not seen clinical reason to do so. It seemed possible, he said, to explain all the benefits of heliotherapy as being produced partly by suggestion, partly by the increased metabolism induced by the very free exposure to the air which heliotherapy involved, partly by surface hyperæmia and the resulting lymphorrhœa, and partly, as in rickets, by the formation of vitamin D through the action of the sun's rays on cholesterol.

### *Phototherapy.*

Dr. Pugh then discussed the influence of artificial light in treatment, and the importance of separating subjective from objective manifestations. The subjective effects, in his experience, were more marked than the objective. Suggestion played some part, no doubt; but this was not all. Dr. Hill had said that there was no increase in metabolism. Could the stimulation of nerve-endings by the rays act reflexly on internal processes, and so produce the feeling of well-being which made this treatment so much appreciated by the over-worked, the neurotic, and the run-down? On the more serious forms of neurasthenia it had no permanent effect so far as his own limited experience went; he had treated two cases only, one resulting from war shock, the other from accident. On the objective side three effects had to be considered: (1) hyperæmia of the surface, which conceivably might lead to reduction of high blood pressure by vaso-dilatation, lymphorrhœa (which would assist in the healing of ulcers and superficial sinuses), and improvement in abnormal skin conditions—e.g., eczema, psoriasis, alopecia areata, and lupus; (2) production of vitamin D by the action of rays on cholesterol; and (3) the short-lived increase in *hæmo-bactericidal* power.

Dr. Pugh demonstrated a large number of photographs of patients before and after exposure to from 30 to 80 carbon-arc baths. In a glandular abscess of the neck, with reddened undermined skin over it and a small discharging sinus, the undermining had continued to extend. In similar cases in which the undermined skin was cut away and the lesion scraped, and other superficial sinuses and ulcers connected with tuberculous phalanges and tarsal bones, healing was definitely hastened by the light bath, especially when there had been previous scraping. It was interesting to note that the Finsen Institute had *two operating theatres* for 149 beds. Sinuses connected with deeper structures—e.g., spine and hip-joint, in which help was especially desirable—showed absolutely no improvement; an old empyema sinus similarly remained unchanged. In some cases the Murray Levick red-ray lamp was used on superficial ulcers, and appeared as efficacious, if not more so. A severe case of acute general eczema, after two months' ineffective treatment by ointment, was given carbon-arc irradiation; 29 baths in three months got it well under control, and a month later it was quite cured. Two other cases of eczema still under treatment showed little or no improvement. A case of psoriasis had not improved after 40 carbon-arc baths; one of the larger patches was then blistered by the Kromayer lamp, and it had completely disappeared when the scab separated. One child with a localised patch of lupus on the cheek showed, beyond a disappearance of the scaliness, no definite improvement at the end of two months in spite of 17 general light baths; the patch was then blistered with the Kromayer lamp three times at intervals of about three weeks, the arc bath being continued; after six weeks' rest from treatment there was marked improvement, only a few active nodules remaining. Several other cases of more extensive lupus affecting the nose and limbs, which had been given many carbon-arc baths, showed no benefit beyond a cleaning up of the surface.

Dr. Pugh drew attention to statements by several dermatologists about the limitations of usefulness of the Finsen lamp in the treatment of *lupus*, and to the suggestion of Mr. Sampson Handley that, in any method of treatment, radium γ rays should be used around the circumference of the area to excite an aseptic lymphangitis and obliterate the lymphatic vessels around the infected area, so as to provide an insuperable barrier to spread. This suggestion, he thought, might be of value, as he had used radium γ rays in the treatment of tuberculous adenitis during the past three years with very satisfactory results. As regards rickets, he thought it would generally be impracticable to withdraw a mother from household duties at the busiest time of the day to take her child regularly to a light treatment clinic; and it was probably unnecessary, as the administration of a sufficient quantity of cod-liver oil at home answered the purpose in the majority of cases, particularly if it was adopted as a preventive measure during the autumn and winter months.

### *High Blood Pressure: Infectious Diseases.*

Dr. Pugh's experience of the use of general arc baths in the treatment of high blood pressure was, he said, naturally very small. In one case, however, the pressure, which had been reduced from 180 to 140 mm. by six weeks' rest, fell to 136 mm. after a course of carbon-arc baths; at the end of a second course, given after a long interval, the pressure was 150 mm. In another case treatment was commenced only a fortnight before; the pressure fell 4 mm. from 105 mm. after the first light bath, and then 10 mm. as the result of epistaxis; at the end of the fortnight, during which time the patient had had six light baths and several attacks of epistaxis, the pressure was 150 mm. Both patients declared that they felt better for the treatment and had lost their headaches. It had been said that light treatment increased the hæmo-bactericidal power, and that this might put up the general resistance of the body to disease.

So far as infectious diseases were concerned this had not been confirmed at Carshalton. Epidemic catarrh and chicken-pox, when introduced into wards, had affected patients indiscriminately, whether they were receiving light treatment or not. This was compared with the influence of open-air treatment in the limitation of spread of infection. Measles had been recently introduced into one ward of a block containing young recumbent patients, 30 of whom were being treated indoors in two wards and 30 in verandahs. The disease spread into the other ward, and of the 22 indoor children who had not previously had measles, 21 caught it; none of the 13 verandah patients who had not had measles developed it, although they were looked after by the same nurses as the indoor children. Vaccination had not been influenced by courses of light treatment, whether these were given before or after, or both. He had been informed by Dr. T. H. Woodfield, of the Park Fever Hospital, that his impression, after using ultra-violet light in the treatment of 20 cases of whooping-cough, was that good was done in the early stages, but that when well-established the disease was not influenced by light treatment; his results had been inconclusive for diphtheria carriers.

Dr. Pugh trusted that the introduction of phototherapy into town hospitals would not lead to delay, however short, in the transfer of cases of surgical tuberculosis to country institutions, as it was obvious that it had very serious limitations as compared with open-air or sunlight therapy.

---

# PUBLIC HEALTH IN PERSIA.

## 1914–24.

BY A. R. NELIGAN, M.D. LOND., M.R.C.S., D.T.M. & H. CAMB.,

PHYSICIAN TO H.M. LEGATION, TEHRAN; BRITISH REPRESENTATIVE ON THE PERSIAN SANITARY COUNCIL.

(*Concluded from p. 694.*)

## PART III.

### *Medical Practice.*

As is only natural in a country which produced Avicenna and Rhazes, the practice of medicine is a popular profession. Tehran, for instance, has a doctor for every thousand inhabitants. There are, on the other hand, country districts, hundreds of square miles in extent, where there are no doctors at all. Before the passing in 1911 of a law obliging all students to take the State diploma through the Government Medical School, permits to practise could be obtained by apprentices of native doctors and assistants trained in the various foreign hospitals. The "authorised" doctors (médecins autorisés) still form the bulk of the profession. A second class are Persians qualified in their own or foreign medical schools (médecins diplomés). Most of those who have gone abroad have studied in France; a much smaller number have qualified at Beyrout, in England, America, or Germany. Foreigners are expected to register their diplomas at the Ministry of Public Instruction. They include medical officers of Legations and Consulates, doctors in Persian employ, missionary doctors, medical officers of commercial undertakings such as the Anglo-Persian Oil Company, and private practitioners. This last class practically did not exist before the Russian revolution; there is now in the north of Persia a considerable number of Russians and Armenians with European qualifications.

Persian practice is largely medical. There are few surgeons, though in many towns there are men who extract cataract and cut for stone. While old remedies are in constant use and the distinction between "hot" and "cold" much insisted on by the older practitioners and by patients, foreign drugs such as antipyrin, phenacetin, aspirin, calomel, boric acid, zinc sulphate, sublimate, salines, and, of course, quinine, are much employed and their names and uses well known by the laity. A striking feature of Persian practice is the avidity with which the latest pharmaceutical products of enterprising firms in Europe are used. The country is flooded with samples and circulars names of certain reputable firms, however, are well known and their preparations highly esteemed. It is only within the last three years that X ray examinations and treatment have been possible in the capital, and there are now two outfits. These, and the opening of a public pathological laboratory in 1921, have done much to improve methods of practice.

There is no dental school and there are very few foreign dentists. Again the capital is more fortunate in this respect than the rest of the country. Locally trained dentists are now required to pass a simple examination.

A Medical Debating Society was formed in Tehran in 1924 with Dr. J. Scott, medical superintendent of the Indo-European Telegraphs, as President. It holds fortnightly meetings during the spring, autumn, and winter, and has formed the nucleus of a pathological museum.

Chemists' shops are numerous, but highly qualified chemists few. During recent years regulations have been drawn up, so that at present the better class will not supply poisons or narcotics without a doctor's order, and a record has to be kept of sales. In 1910 a law was passed regulating the practice of pharmacy and obliging chemists to take out permits from the Ministry of Public Instruction. They were given to three categories: (1) those who had European diplomas; (2) those who had worked continuously in a reputable pharmacy during the previous five years; (3) those who could pass a simple examination locally. In 1922 a school of pharmacy was opened in connexion with the medical school, and all would-be chemists must pass through it. Unfortunately the school is poorly equipped.

### *Irregular Practitioners.*

The number of irregular practitioners is legion. Every woman is an authority on medicine and uses remedies such as castor oil, cassia, manna, infusions of violets and decoctions of various herbs, and opium. Some women specialised in the treatment of syphilis by calomel fumigations, but since the introduction of salvarsan less has been seen of their results. There are bonesetters, generally butchers, who adjust displaced bones and produce disastrous effects in the case of fractures. The barbers cup, bleed, extract teeth, do arm-to-arm vaccination, and perform circumcision. Massage is done by the bath attendants. Charms are in regular use, and the choice of doctor or treatment is frequently decided by a reference to the Koran or by counting beads. The midwives make internal examinations and introduce strange substances to hasten labour or provoke abortion. The latter practice has become regrettably common in the capital, and is not always the work of uneducated women.

Apart from the regulations about diplomas there are no laws governing the practice of medicine, except one to the effect that the component drugs of a prescription must all be clearly indicated. Post-mortem examinations, like dissection, are contrary to the religious law.

### *The Opium Question.*

The opium question has become one of the most difficult of the many problems which the Nations in Council are striving to solve. For a producer country like Persia, with impoverished finances and many thousands of addicts, it is impossible to exaggerate the importance of the fact that international efforts are being made to limit the cultivation and the abuse of opium. Only a short résumé of this complicated question can be given in a paper on matters of public health, and it should deal chiefly with its medical side and with the problem of the abuse of opium and of its limitation, as it affects Persians. Economic questions are, however, so inextricably bound up with both these aspects that it will be impossible not to mention them.

### *Abuse of Opium in Persia.*

It is difficult to say when opium was introduced into Persia, and when its use for other than medical purposes started. Since, however, it is believed that the poppy plant reached China from Arabia (the Chinese word for opium is a corruption of the Arabic *afiyun*), it does not seem necessary to look further than Persia's neighbour. Moreover, the famous Persian physician, Abu Ali Sina (Avicenna), who lived in the tenth century, when writing of the use of opium, warned his readers against its abuse. There can be no doubt, then, that both have been known for at least some thousand years. Opium smoking is, however, of comparatively recent origin; it was introduced from India into East Persia rather more than 100 years ago, and there are parts of the country where the habit was not known as recently as the end of last century.

To-day the devotees of opium in Persia may be numbered by hundreds of thousands in all ranks of society. It is impossible to give even approximately exact figures, but in 1914 the Municipality of Tehran estimated the number of smokers alone in the city as 25,000. At present some 80 lb. of prepared opium are liberated every day in Tehran (not all for use locally), and probably an equivalent amount is put into circulation fraudulently. The proportion of one smoker in ten of the population is almost certainly an over-estimate for the capital, but in the case of some towns in, say, the province of Khorassan, it would as certainly be found to be much higher.

The users of opium may be divided up into the following groups:—

*The Eaters.*—1. Those who take a small quantity (½–1 gr.) once or twice a day. The drug is used as a sedative tonic just as tobacco is used. 2. Those who take opium for its well-known effects. The allowance may reach three, four, or more drachms a day.

*The Smokers*, the larger of the two groups, comprise: (1) Occasional smokers of prepared opium. (2) Regular smokers of prepared opium, by far the most numerous class. Two drachms is an average quantity. (3) Smokers of *shireh*, a mixture of prepared opium and the burnt residue left in the opium pipe. In parts of Persia the *shireh* smokers are more numerous than the smokers of prepared opium; they are physical and moral wrecks. (4) Smokers of *negari*, a mixture of the burnt residues of opium and of *shireh*. Inconsiderable in numbers. The wide-bored stem of the *negari* pipe, thoroughly well incrusted with the burnt residue after use by generations of smokers, is said to be without price, and to produce its effect by simply drawing air through it! Good prepared opium contains 10–12 per cent. of morphine, *shireh* containing 10 per cent.

While making all allowance for the ingestion of opium in "tonic" doses for the moderate smokers, and for the fact that, in a country where doctors are few and far between, opium is a great solace to people in pain or attacked by malaria, there can be no doubt that the opium habit is doing much harm. It is, moreover, increasing. These statements are not merely the result of personal observation; they represent the considered opinions of Persians competent to judge, and they lead up to the question of the limitation of the abuse of opium. Here it is necessary to give some facts from the economic side of the Opium Question in Persia.

### *Production and Restriction of Opium.*

Roughly 870 tons of opium sap were produced in the year 1923–24. Of these 200 tons were exported, chiefly to the Far East. If allowance be made for under-valuation and smuggling, opium represents 20–25 per cent. of the total value of Persia's exports, not including oil.

The good quality of Persian opium, the demand for opium and morphine in the Far East, and the high prices obtained, have led to a great increase in opium poppy cultivation in recent years. No doubt, too, the prospect of international legislation being enacted to lessen the opium evil prompts cultivators to make hay while the sun shines. By law the whole of the opium sap should enter the Government warehouses. The question of Government control is a difficult one in a country as large as Persia, with a scattered population and difficult communications, and especially in the case of a crop so easily grown as opium; but it is slowly though steadily being improved. The opium sap for use in the country is worked up into sticks (a process in which it loses about one-third of its weight), a banderole is attached, and the merchant on regaining possession pays the Government tax. Customs duty has to be paid on the opium cake for export. The total opium revenues for 1923–24 amounted to 8 per cent. of the total revenues of the country. The opium trade employs many thousands of people. In the town of Isfahan it is estimated that at least 25 per cent. of the population lives by opium. The annual average return to landowners and peasants on the opium crop is about £2,100,000 at par. Transport is difficult and costly in Persia, but opium, on account of its small bulk and high value, presents no difficulties. It always fetches ready money—in fact, it takes the place of money. The crop is easily raised and taken and it requires water only at the season when water is plentiful.

These few briefly stated facts show how difficult the problem of restriction of the cultivation and abuse of opium is in the case of Persia. The abuse of opium is recognised by Persians in all classes of society as a national calamity. Their Government has stated, through its representative in the recently held Opium Conferences, its readiness to coöperate in the effort to reduce the evil both at home and abroad. It has introduced or proposed legislation of its own initiative which is directed to that end, and has expressed its willingness to go farther. The Sanitary Council has been instructed to make recommendations for the control of opium-smoking and of the sale of opium, cocaine, and their derivatives. The Governor of Bujnurd, in 1923, took the remarkable step of forbidding opium poppy cultivation in his district. On the other hand, Persia has entered on a period of intense desire to develop her resources; her revenues are not sufficient to meet her needs, and any diminution in the volume of her opium trade would mean serious losses. The solution, already put forward officially, probably lies in the gradual replacement of the cultivation of opium by other crops or trades. There are, however, great difficulties in the way—financial, economical, and physical.

The complexity of the question of suppressing the use of opium in the East is great, and, in the latter end, one is left asking what will be the result if it be achieved. Certainly in the case of Persia, where the use of opium residue as opposed to prepared opium is comparatively limited, to see opium replaced by morphine, cocaine, or alcohol would not be an upward step.

### *Hashish, Morphine, and Cocaine.*

It is difficult to learn the extent of the abuse of hashish. Addicts are numerous in Khorassan and among the dervish fraternity. The drug is smoked in different ways and may also be ingested. There is no Government control, but it is intended to pass laws forbidding the cultivation of the plant and its use. Hashish and opium are occasionally smoked together (*Ruh' ul ajaneh:* the soul of Satan).

In spite of the fact that the Governor of Nishapur reported in 1914 that morphine was being used extensively by injection no further evidence of the practice has been received. The authorities confiscated some parcels of syringes at about the same time. As long as opium for smoking is to be had easily, it is unlikely that the syringe will oust the pipe with its elaborate ritual and the atmosphere of sociability which it creates. It is reasonable to suppose, however, that increasing interference with the liberty of the subject in the matter of opium might lead to the abuse of so easily smuggled a drug as morphine.

The question of narcotic drugs has been examined by the Persian Government since 1911. In 1919 the Ministry of the Interior consulted the Sanitary Council about regulations for the sale of morphine. In 1920 the Ministry of Foreign Affairs reported a great increase in the quantity of cocaine imported and asked the Council to fix the requirements of doctors. As a result in 1922 the Council was charged with the issue of permits for the importation of opium derivatives and cocaine and its similars. The amount of morphine which any one chemist or merchant might import at a time was fixed at 20 g. All parcels were to be sent to the Council's offices for control and distribution, a cumbrous system which has caused trouble with importers living near the frontiers.

Cases of cocaine addiction have not been seen even in the capital except in one or two Persians who have learned its use in Europe.

### *Alcohol.*

Theoretically there should be no need for a paragraph with this heading in a report on a Mussulman country; but the land of Sa'adi, Hafiz, and Omar Khyam has always been famous for its wine, and in modern times native alcohol (*arak*) has been extensively made. There is, however, no alcohol problem at all comparable with that found in countries further west. Be that as it may, it is interesting to note that in 1921 the revolutionary cabinet of Said Zia ed Din made a courageous attempt to introduce prohibition, and the revolutionary programme was announced at a State banquet at which water, fermented milk, and fruit syrups were the liquid refreshments. It was a difficult policy to carry through on account of the stocks of wine in existence and of the large number of persons who gained their living by wine and *arak* making. In the same year Persia was represented at the International Conference on Alcohol held at Geneva. In 1923 the Ministry of Finance proposed regulations for restricting the import of alcohol by foreigners, and the Sanitary Council recommended that its use should be limited to medical and industrial purposes. At present there are no restrictions on the import of foreign wines and spirits, or the making of wine, although there is a small tax on each load of grapes for use therein. *Arak*, which is made from raisins, is submitted to a heavy tax, which is foregone in the case of alcohol for medical and pharmaceutical purposes. The distilleries in Tehran have been centralised for purposes of control. It is to be noted that the existence of considerable European, Parsi, Armenian, and Jewish communities makes the manufacture and sale of wine and *arak* an easy matter.

### *The League of Nations and the Sanitary Situation.*

As a result of the appeal, to which reference was made in an early paragraph, the League of Nations, in July, 1924, sent out Dr. John Gilmour to report on the sanitary situation. He spent several months in the country, and his preliminary report has reached the Persian Government. An interesting recommendation which it contains is that selected Persian doctors should be sent to Europe for instruction in hygiene, under the supervision of the Sanitary Section of the League.[1]

A society, called the Society of the Red Lion and Sun, was formed in 1923 to carry out humanitarian work comparable to that done by the Red Cross, Red Crescent (Turkey), and Red Sun (Japan) Societies. It has been officially recognised by the International Organisation of Red Cross Societies.

### *Innovations.*

Before concluding, two interesting changes that have taken place in Persia of recent years, but of a less obviously medical nature than those recounted above, will be described. One is the increasing use of the potato, which, if continued, will provide the country with a valuable addition to, or substitute for, the usual diet of bread or rice. The other is the introduction of field games. Polo and Association football have been played in Persia by Englishmen for many years. Polo, originally a Persian game, has now become very popular among the officers of the army and tournaments are held. Football has within the last four years made great progress, and in the capital regular competitions are held for clubs and for schools. The terms used are the English ones, and the keenness is intense. In the autumn of 1924 an elaborate athletic meeting was held in Tehran. Bicycling has also become very popular.

All who have come in contact with young Persians will realise what an enormous effect for good the introduction of active sports will have on their health and morale. It is for this reason that the subject is worthy of notice as of real importance to the public health of the country.

### *Conclusion.*

A review of public health questions in Persia during the past 11 years shows that the most important problem is presented by malaria, and that so far no prophylactic measures on a large scale have been attempted.

As regards the great epidemic diseases certain towns on the southern sea-board in communication with India, the Arabian coast of the Persian Gulf, and Mesopotamia, are liable to limited outbreaks of plague, but the country as a whole presents natural obstacles to the spread of that disease. None of the plague centres described in the past have shown signs of activity, and no new centres have appeared. Cholera, on the other hand, once introduced has been difficult to arrest, but again is not endemic. An imported case of cholera at Abadan gave rise to a local epidemic in 1924 which spread to Mesopotamia. This is the only instance, during the period under review, of an epidemic originating in Persian territory and spreading to a neighbouring country. Variola and typhus fever are endemic, and an extensive epidemic of the latter occurred in 1917–18 after a year of drought and famine. Relapsing fever became epidemic at the same time, and, as an occasional sporadic case is seen at long intervals, must be counted endemic.

Progress in sanitation has been made in the capital, and a public vaccination service for the greater part of the country, and now in its fourteenth year, has met with considerable success. The local preparation of vaccine lymph is a big step in advance.

Epizootic diseases have become a serious problem. Anthrax has long been known to exist and now the occurrence of cattle plague has been proved.

The abuse of opium has become very serious from the point of view of health.

Field games have been successfully introduced.

The public health is in the hands of young Persians with Western training, but no special qualifications for this kind of work. Their plans for an organised health service are praiseworthy, but are hampered by lack of funds and, above all, of properly trained medical officers. The quarantine service in the Persian Gulf is, however, well staffed and organised.

The Persian Government has uniformly done its best to give effect to the proposals made to it by its advisers and has fulfilled its international obligations. The population and the health services are, however, suffering from the failure to make radical changes in the organisation of the State Medical School and to make the teaching more practical and more modern.

## FRENCH DOCTORS AND THE FALLING FRANC.

THERE used to be an old saying that the only way to grow rich was to pay one's debts. This is true in the sense that no man is really rich so long as others have rights over his property. A writer in *Paris Médical*[1] now points out that this saying is, alas, no longer true in France. He who pays his debts in Paris to-day grows poorer, not richer. The man who paid his tailor's bill in September would have done better to put off paying it till December, when the rate of exchange and the corresponding value of the franc had fallen. This curious and unfortunate state of affairs has placed French doctors in an embarrassing situation. Formerly in reference to a code of elegant manners, it was not considered proper for a doctor to send in his bill before a decent period had elapsed after the consultation. Certain families, arbiters of punctilio, were outraged if he dared to present his account before three, four, or even five years had gone by. The price of politesse in those days, however, merely amounted to a few francs' interest lost, and that, we may suppose, was more than made up in increased prestige. But now the situation has completely changed. In little more than a year the £ has risen from 80 to 130 francs—that is, the franc has lost almost half its value. A doctor who, in January, 1925, might have bought himself a new suit with a patient's fee paid on the spot, could hardly buy himself a dinner with that same fee paid in January, 1926. Doctors are bad accountants, and it has taken some time for them to realise the situation. For months past their housekeepers have been asking for more and more money to pay for lettuces and cauliflowers, and they have grumbled a little at the high prices, but they have hardly given serious thought to what these rising prices really meant. Now things have reached such a pass that they are forced to face the situation. Doctors have stomachs, like their patients, and stomachs have certain definite functions to perform. Many French medical stomachs, accustomed to burgundy, have perforce now to be content with vin ordinaire. The only practical solution of this economic crisis, thinks the French writer, is to follow the example of many surgeons and specialists, and to ask boldly for payment of fees on the spot. This seems a sensible solution of the problem, and some doctors on this side of the Channel might be grateful if their French colleagues set the fashion of cash, not credit.

## THE TOILET OF THE MOUTH.

WE have received from Mr. E. M. Uncé, of 30, Swan-road, Harrogate, three articles for use in the toilet of the mouth which deserve trial. The first is a tooth-brush designed to clean the front and back surfaces of the teeth at the same operation and consists of two tooth-brushes with the face of the bristles opposed to each other, the handles being joined together with a U-shaped spring. Pressure put upon the spring regulates the distance between the two surfaces of the brushes between which the teeth pass as the brush is moved backwards and forwards or up and down. The second is an instrument for cleaning and massaging the gums, and consists of two small soft rubber rollers mounted on wire handles. The handles are so shaped that the rubber rollers can be made to press on the gums at any point as well as upon the roof of the mouth. The third article is a saline tooth-powder for employment with either the massage instrument or with the tooth-brushes, and is pleasant in use. The registered trade name of all three articles is "Gummette."

## NEW INFECTIOUS HOSPITAL FOR HULL.

THE Health Committee of Hull Corporation has approved plans for a new infectious hospital at Cottingham, which will cost £85,000. The medical officer states that Hull compares unfavourably with other large towns in regard to accommodation for infectious diseases. The number of beds normally provided at the City Hospital is 116, but there were recently 133, while the cubic feet per bed specified by the Ministry of Health would permit of only 56.

## WESTMINSTER HOSPITAL.

*To the Editor of* THE LANCET.

SIR,—I notice that in your issue of March 20th you state that the out-patient attendances at Westminster Hospital are 3·5 per cent. more than in 1922. This should read 35 per cent.; the correction makes the substantial increase in our out-patient work apparent. Your statement that subscriptions have increased by 58 per cent. and donations by nearly 100 per cent. may, perhaps, give a misleading impression of the financial position of the hospital. This statement was a quotation from the report made by Mr. E. H. Hoare, our treasurer, at the meeting of the quarterly board, and he went on to say that, although the public were showing their appreciation of our great work by increased support, yet that support was still quite inadequate to the greater needs of the hospital, as was evidenced by the fact that in 1025 there was a deficit of £2649.

I am, Sir, yours faithfully,
CHARLES M. POWER.
Secretary.
March 24th, 1926.

# Lumleian Lectures
ON
# ENDOCARDITIS.

*The Second* Lumleian Lecture in 1926, delivered before the Royal College of Physicians of London on March 25th,*

By Sir THOMAS HORDER, Bart., K.C.V.O., M.D., F.R.C.P. Lond.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

## Non-microbic Ætiological Factors in the Production of Endocarditis.—(*Cont.*)

### *Physical and Emotional Stress.*

But if we have been cavalier in our consideration of congenital defects and the anatomical strain which they impose upon these delicate structures, situate as they are at the very centre of the hydraulics of the circulation, may we not also have been somewhat cavalier in regard to strain of a functional kind? It has been the custom of late years to minimise the factor of physical and emotional stress in general in cardiovascular disease, and therefore it has been largely discounted in the production of endocardial changes. This is a material age, and we have become accustomed to discount *functional* elements in the ætiology of organic disease. We have been told that the healthy heart cannot be damaged by volitional effort. But whose heart is "healthy"? If a heart is found to be damaged after effort, then the onus of the damage is laid at the door of toxic agencies. But are we not all of us potentially, if not actually, "toxic"? And if this be so, does the doctrine of the heart's immunity from self-imposed strain carry any more practical application than that it is desirable, in order to reduce the effect of the strain to a minimum, that we should see to it that we are as little "toxic" as possible?

It is necessary to distinguish between sudden and occasional strain on the one hand and prolonged strain, on the other. There seems good reasons for believing that both physical and emotional strain, if prolonged, may lead to endocardial disease, both of the sclerosing variety and, with or without this, of the active bacterial type. Since prolonged strain is inseparable from fatigue, this element may also be included in this group of ætiological factors.

### *Fatigue.*

The recent experiences of those who have had charge of ex-soldiers suffering from endocarditis of the bacterial sort throws much light upon this matter. Reports concerning these cases are to hand from careful observers in nearly all the belligerent countries, but are not yet complete in many important points. So far as the observations go, however, we have strong confirmation of the view taken here. The cases reported have been almost entirely aortic in disposition, there has for the most part been no evidence of previous disease of the valves, and the type of soldier affected, and his war record, suggest strongly that the factor of strain has been considerable. In this country Starling and Carey Coombs have made memorable contributions on the subject. Starling, in a report on 52 cases of infective endocarditis in ex-soldiers, in half of which the disease was of the chronic type, says of them:—

> "The disease occurs in individuals of fine health and physique who have had little or no previous illness. The majority of those suffering from it have undergone a considerable degree of physical stress—e.g., those who were serving in the fighting line in the years 1916–17. The infection is primary in the endocardium. The post-mortem appearances show no evidence of previous rheumatic endocarditis."

Carey Coombs in his equally important paper is led to almost identical conclusions. He says, as the result of his analysis of 30 cases of post-war chronic endocarditis of the bacterial type—

> "The predisposition of the ex-soldier to endocarditis lenta is not due to infections of the heart prior to enlistment, since approximately four-fifths of the cases, even after the Ministry of Pensions had scrutinised their histories, failed to disclose any evidence of such infections. . . . The facts as to lesions and diseases contracted during service are, of course, open to the criticism that it is quite impossible to assess in figures the liability to injury of the various 'portals of entry' of infection; but it does seem reasonable *to conclude that the reason why soldiers have become* victims of endocardial infection does not lie in their liability to be invaded by micro-organisms through any particular tract. . . . There is, however, a very remarkable fact, only imperfectly presented by the statements, that 80 per cent. of the men were engaged in the more strenuous forms of military service and that the average duration of service was 3·05 years, or nearly three-fourths of the whole length of the war. The fact is one which is not susceptible of arithmetical statement. It is this, that almost without exception the men whose military service was followed by the development of endocarditis lenta were *men of fine* physique and morale; men who joined the army early, served with all their might, and exerted themselves to the utmost limit of their physical powers. . . . Looked at from the obverse side, the same fact is equally striking. At the bases and elsewhere, both at home and overseas, there were large numbers of men of indifferent physique serving in the army; yet I have not so far encountered a single example of chronic endocardial infection amongst such men."

Carey Coombs does not miss the obvious point that excessive *fatigue may predispose* the body to infection, and thinks a biochemical link between fatigue and infection may be suggested by Walker Hall's work on the effect of dilute acids in accelerating blood cultures *in nutrient broths.*

Strain and fatigue overlap with *arterio-sclerosis,* with which in most cases *hyperpiesia* goes hand in hand. Upon this factor in the production of chronic *endocardial disease I do* not propose to dwell.

I agree with Irving Simons, to whom we owe a masterly critical review of the whole subject of endocardial infections up to the year 1914, *that the* lesions occurring in the heart in cases of the so-called *cachexias* lack clinical significance, and are to be regarded rather as marantic thromboses than as true endocarditic manifestations. This statement refers to most of the positive post-mortem findings in cases of chronic nephritis, tuberculosis, cirrhosis of the liver, and carcinoma. They are to be distinguished, however, *from* cases of terminal septic endocarditis occurring in patients *suffering* from *these* same diseases, a class to which, in my original survey, I included in the "latent" group. Although they usually are *latent,* it would be better to call them "terminal," since the word latent is more properly used for those cases of chronic infection which only come under observation as the result of one of the *accidents incident to the* disease, and especially embolic infarction.

### Septic Endocarditis.

I now pass on to consider the large and important but heterogeneous group of cases of [illegible] variously termed "ulcerative," "malignant," "infec[illegible]tive," or "bacterial." The limits of [illegible] ill-defined. At one end of a possible [illegible] they may be placed the [illegible] group. Poynton and Paine [illegible] other workers, describe a [illegible] carditis, considering the [illegible] in their judgment a specific streptococcus (the *Diplococcus rheumaticus*), is responsible for such cases. At the other end of such a series are cases in which the endocardial lesions may be regarded as little more than intracardiac thrombosis occurring in the course of a pyæmia. The present nomenclature is avowedly very unsatisfactory. "Ulcerative" has the double objection that, even if we leave out of account for the moment Poynton and Paine's cases of malignant rheumatism, a process of ulceration occurs in severe forms of acute rheumatic endocarditis, as may be seen not infrequently in the post-mortem room, whereas by no means all cases of the bacterial group are associated with ulceration. Indeed, the absence of ulceration is an important feature in some of the more chronic cases. "Malignant" is an ugly and forbidding word to use, and however high the mortality in the fully-fledged cases within this group may be, some patients do certainly weather through. To both the words "infective" and "bacterial" the objection applies equally—that the rheumatic cases are presumably of this nature, despite our ignorance of the cause of the infection, and the syphilitic cases certainly are. The tendency during recent years to change the word "infective" for "bacterial" is curious, seeing that we have no knowledge of infections which are not bacterial. Beyond sharing the general dissatisfaction with any and all of these names, I am not anxious to introduce a new one. But I have a leaning towards a still older name than any of those now used, reactionary though it may sound to speak of "septic" endocarditis. The word commits us to nothing in regard to pathogenesis, yet is expressive of the main differential features between this form of endocarditis and the rheumatic and syphilitic forms. Irving Simons regards the term "septic" as unfortunate inasmuch as the lesions in many cases are not suppurative. But suppurative is by no means a necessary part either of acute or of chronic sepsis. Witness our use of the term in such conditions as "puerperal sepsis" and "focal sepsis"; in neither of these expressions does the word "sepsis" necessarily connote suppuration.

---

* The first lecture appeared in The Lancet last week.

Unfortunately the confusion in words does not end here; confusion has of late years also invaded the terms by which we designate the type of disease as regards the intensity of the morbid processes involved and the duration of them. Although the words "acute" and "chronic," like a good many very common words, cannot be accurately defined, there is general consensus of ideas as to what they mean when applied to diseases. They are a convenient estimate of the two combined qualities already mentioned—intensity and duration. Now everybody seems agreed to the use of the word acute in relation to certain cases of bacterial infections of the type I am now discussing, but the cases that are not acute have been called "chronic," "subacute," and "slow" by different authors. As between "chronic" and "slow" there seems to be no difference. Schott Müller's account of the cases which he described under the name "endocarditis lenta," and which appeared in 1910, the year following the accounts contributed in this country by Osler and myself, makes it clear that he was dealing with the same kind of case which we called "chronic endocarditis." Individual cases of this chronic type had been described earlier, as by Bristowe, Lenhartz, and others. In the same year Libman introduced the term "subacute bacterial endocarditis," and by a rapid series of papers, embodying observations and reflections of fundamental importance, has succeeded in establishing this term, for a time, as synonymous with both the earlier names.

Most of those who have considered the matter, and have contributed to our increasing knowledge of the subject, fail to distinguish between the cases originally designated "chronic" and Libman's subacute cases. And so it comes to pass that these two terms are, for the most part, used indiscriminately. Strangely enough, if there is any tendency to make a distinction between these two terms it is to use Libman's new term for a class of case which, on analysis, seems to be of even slower development and less intense symptomatology than the class of cases formerly called chronic. I shall refer to this point again, because of its important bearings upon pathogenesis.

*Acute septic endocarditis* was recognised clearly by Wilks and others. Wilks introduced the excellent term "arterial pyæmia," and the words very aptly express the main features of the disease. Little or nothing has been added to our knowledge of this group of cases since Wilks's time. The heart and heart valves share in a general infection. The micro-organisms concerned are highly virulent in character: *Staphylococcus aureus*, *Streptococcus pyogenes* (*vel hæmolyticus*), the pneumococcus, and less often the gonococcus.

The onset of the disease is usually abrupt, the symptoms severe throughout, fever is high, rigors are common, and the course of the disease is rapid. A few doubtful recoveries occur. Death usually takes place in from ten days to a month, but there are fulminant cases which terminate in three or four days, and some, of less than the ordinary severity, which drag into the second month. The disease sometimes complicates osteomyelitis, erysipelas, pneumonia, and less often some other acute focal infections. I deal with it here thus briefly so as to give my groups of cases more clear definition.

### *Septic Endocarditis of the Right Side of the Heart.*

Amongst the cases of acute septic endocarditis which I have observed of late was one in which the tricuspid valve was affected, and this valve alone. Since I regard the case as presenting the clinical picture to be expected in this somewhat rare condition I will give a brief note of it.

A man aged 42 years was admitted to St. Bartholomew's Hospital on the sixteenth day of an acute illness which was ushered in by shivering and headache. The man was seen by his doctor on the second day of his illness and put to bed, where he had been ever since. He became delirious on the third day and was transferred to a nursing home. About this time a patch of pleuritic friction was noted near the region of the right nipple which disappeared in less than a week. There were no physical signs of pneumonia. The temperature chart, which was brought to the hospital with the patient, showed that there had been a fairly continued fever for four days after the record was begun, the temperature reaching 103–4° F. It fell, but not by crisis, on the eighth day of the illness, and remained nearly normal for three days. It then rose sharply, with a rigor, reaching 104–5°. The delirium, which had subsided with the defervescence of the fever, returned. There was no headache. From the twelfth to the sixteenth days there were daily rigors, with profuse sweats. On admission the patient was very ill, with low delirium, dry cough, and slight cyanosis. Examination of the chest yielded a soft systolic bruit near the apex, and a few rhonchi over both lungs. There was a leucocytosis of 10,800. A lumbar puncture gave normal fluid. A blood culture was sterile. Agglutination tests were negative. Complement-fixation test for T.B. was negative. There were no choroidal tubercles seen. No abnormal coliform organisms were found in the stools. The urine was sterile. The spleen was not palpable. No petechiæ were present. Rigors continued almost daily with high quotidian intermittent fever. On two separate occasions definite areas of crepitation, with soft pleuritic rub, were found, one in the right flank and one in the left axilla. There were no sputa. The frequency of the respirations was constantly raised. These, and the persistence of the apical systolic bruit, were the only physical signs elicited. Two further blood cultures were negative, but on the thirty-third day of the disease the blood yielded a growth of pneumococci. The patient, very ill at all times, died on the thirty-fifth day of his disease.

At the post-mortem examination recent vegetations of the septic type were found on the tricuspid valve, and both lungs contained recent infarcts. There was about a pint of blood-stained serous fluid in the right pleural cavity. This fluid and the heart's blood both showed pneumococci in film preparations.

The chief diagnostic features in a septic endocarditis of the right heart, whether tricuspid or pulmonary, is the association of the signs of endocarditis with multiple pulmonary infarction. The intensity and the duration of the disease process depend, as in left-sided cases, upon the virulence of the infecting microbe. The case just mentioned, being pneumococcal in nature, approximated to the acute forms of septic endocarditis. In a case which I included in my first series the micro-organism was a salivary type of streptococcus, and the infection was grafted upon a congenitally stenosed pulmonary orifice. The patient was a young adult, and her illness dated from the extraction of a septic tooth under local anæsthesia. In the first three months of her disease she had 22 attacks of pleurisy. Although she was known to be the subject of congenital heart disease of a mild type, the real nature of the disease was not recognised, and the repeated bouts of pleurisy, from which, however, she seemed to recover well, and a persistent pyrexia, led to her being sent to a tuberculosis sanatorium. Eventually her blood was cultivated and a streptococcus of the type *S. salivarius* was isolated. After an illness lasting for some nine months, and very thorough treatment, she recovered.

### *Intermediate Cases.*

Between this group of acute cases and the group of chronic septic cases which I shall take in more detail there occur cases which I originally termed "subacute"—that is, cases in which the onset was less abrupt, the symptoms less dramatic, and the course less rapid. The causative micro-organisms are less virulent; the gonococcus and the pneumococcus are found in them at times, but more often the cocci approximate to those found in the chronic cases. Those cases termed by Lenhartz and by Poynton and Paine "malignant rheumatism" are of this class. So also, quite frequently, are those young adults who give a clear history of rheumatic fever in childhood or in the teens, and who present clear signs of residual valvular disease. The duration of these cases is from about three to six months. In view of the present confusion in the use of the term "subacute," I think it better to give no name to this group, but to be content to regard them as an intermediate class between the acute and the chronic cases. In any individual case we may, if we feel unhappy without a label, strain a point and call it chronic.

## CHRONIC SEPTIC ENDOCARDITIS.

It is to the chronic cases, however, that much attention has been directed of late years, and deservedly so. The experience of the ex-soldier in this connexion is, given no other experience, very striking and very helpful in our understanding of endocardial diseases. But in civilian work also there is a growing recognition of the importance of these cases, and of the urgent necessity of detecting them as early in the course of the disease as possible. I shall deal with some of the main points of clinical interest as these have appealed to me, deferring matters of pathological importance until my next lecture.

Chronic septic endocarditis is a disease of adult life; its maximum incidence comes during the third and fourth decades. It is nearly twice as common in males as in females, a disproportion which exists quite independently of the war cases. It is a very insidious disease; it is not at present possible to estimate, except approximately, the date of its origin in the great majority of cases, nor, in those few cases in which we have good evidence of recovery, can we say when it ceased to be an active disease process. But allowing for these things, it is probable that the disease lasts on an average about six to nine months. Not a few cases reach 12 months; and there are reliable records of cases lasting two and two and a half years. Proofs are accumulating that there are recurring cases, also that spontaneous cures occur. Of these cases I shall say more later.

### *Pyrexia.*

The earliest symptoms of the disease are undoubtedly of the toxic kind. *Chills or sweats* are perhaps amongst the earliest recognisable symptom—but an accidentally discovered pyrexia, as following an influenza, frequently leads to observations that discover something seriously wrong in many of the cases. Pyrexia is almost always present at some time or other in the course of the disease. It has little or no recognisable features to guide us. It is rarely high. Apyrexial periods are not uncommon, even when the temperature is taken four-hourly, an important point in the general observations. Rigors are quite unusual.

Exacerbations in the pyrexia are often concomitant with embolic events and especially with embolism in branches of the splenic artery; the attendant peri-splenitis is probably the main source of the fever in this case. That the pyrexia frequently ranges higher with the occurrence of embolic infarction was pointed out by Douglas Powell in his Lumleian lectures in 1899 when he showed temperature charts illustrative of this fact. But I do not know that attention has been drawn to the fact that the pyrexia not seldom falls to a lower level after these exacerbations and remains there for several days. This is not the result of decreased ability to react to the toxæmia, because the patients often feel fitter during this period of lower pyrexia following an exacerbation. It certainly looks as though the mechanism of embolic infarction results in some instances in the manufacture of antibodies to the infecting agent. It would be interesting to examine the patient's blood for these substances by complement fixation or by other means after such a process, and compare the titre with that obtained at other times. I have wondered if the process of embolism in this disease is not sometimes of service to the patient as well as being, at other times, the direct cause of a tragic end. Provided the infecting microbe is not so pathogenic as to overthrow the local resistance altogether and lead to an abscess, which is rarely the case, and provided the embolus does not occur in a vital part like the brain—an all too common contingency—it is quite possible that the extraordinary slowness with which the disease sometimes progresses may in part be explained by such a view. I have been struck by the fact that in the two cases in which I have seen the largest spleens—in both the organ was visible on inspection of the abdomen and its lower border lay well below the umbilicus—the general condition of the patient was well maintained for months together. In one of these cases the spleen had increased so greatly in size during a stay of five months during the winter in the open air at the south of France, that on the patient's return I wondered if she had developed leukæmia. In the other case my opinion was asked because, though a diagnosis of septic endocarditis had been made provisionally, the very large size of the spleen had actually thrown doubt upon it. In this latter case the effect of splenic infarction, as estimated by attacks of pain in the upper and left side of the belly, was seen in striking fashion in the temperature curve, as also was the subsequent improvement in the general symptoms. Remissions in the disease are often attributed to some special line of treatment which is being pursued, such as the use of a vaccine. Before such a conclusion can be accepted it is important to inquire if the remission be not possibly correlated to splenic infarction.

### *Some other Symptoms.*

*Clubbing of the fingers* has, since Cotton's observations published in 1922, become a valuable help in diagnosis. This observer, working in Lewis's clinic, found that of 63 out of 798 cases of structural heart disease in pensioners in whom this sign was present, 44 proved to be cases of chronic septic endocarditis, and of the remaining 19 cases 4 were regarded as doubtful instances of the same disease. This observation has found corroboration from many sources. Starling thinks in the majority of cases the occurrence of clubbing indicates that the disease has been present for some time. It is clear that the association of this sign with acquired valvular disease must put us on our guard.

I referred in my original account of the disease to the frequency of *pains in or about the joints.* I do not think sufficient attention has been paid to these symptoms by subsequent writers. There is a point of great importance in connexion with the manner of their appearance, and that is their suddenness. A second important point is the difficulty that patients often have in locating them. And a third is the absence oft-times of any recognisable effusion when the affected part is a joint, so that I have sometimes spoken of these pains as being arthralgic rather than arthritic. The situations of these pains are very numerous; the regions of the foot and ankle are the most common, then perhaps the hip and shoulder. But the wrist, the back, and the sacrum are not uncommon. The abrupt onset of the pain, and the fact that in not a few cases critical examination discovers a dusky red patch of tender skin in the neighbourhood of the pain in those cases in which the affected part is not a deep structure, makes it probable that the origin of the event is embolic. Many of these pains, even if there be associated swelling, are of quite short duration, passing off completely and leaving no residue, either subjective or objective. In the investigation of a doubtful case, if no history of these pains be given by the patient, inquiry should be made, because it not seldom happens that the event has been considered of no special significance owing to its transient character.

The *ephemeral cutaneous nodes* of French physicians, now generally called after Osler because of the detailed description given of them by our late gifted and lamented colleague, have been proved to possess all the pathognomonic value which he attributed to them. I know of no feature in a suspected case which possesses such dire significance. Again, owing to their fleeting nature, inquiry should be made for these lesions if they are not present when the patient is first seen. No doubt they, too, own an embolic source. The most common situation for them is the pulp of the finger or toe. They also occur on the thenar and hypothenar eminence. I have described analogous lesions as occurring occasionally in the bed of the nails, where a thin splash of red may be seen, accompanied by exquisite tenderness if pressure be made upon the affected part. These nodes arise suddenly, with sharp pain, as though the finger has been pricked; indeed, patients often examine the part carefully to make sure that some sharp object, like a thorn or a splinter, has not been the cause of the sensation. One patient, a typist, found she could not use a particular finger for two or three days because of the tenderness caused by pressure on the keys of her instrument. A few hours after the onset of the pain an erythematous patch appears, pinkish at first, and later dusky red, with oft-times a centre of white skin rather suggestive of an urticarial wheal. There is usually slight swelling of the discoloured skin. The redness disappears, and the tenderness also, in about one to three or four days.

The presence of *petechiæ* in the skin is quite a different sign from that last described; though of much less diagnostic value, it is still very important. As I have pointed out, a favourite and early situation for these lesions is about the neck and clavicles; other common situations are the chest, forearms, legs, and buttocks. Needless to say, two or three scattered iæ may be very easily overlooked unless the possibility of their presence is specially borne in mind and the body is scoured for them in a good light. Like the nodes just referred to, these petechiæ are short-lived. They tend to appear in small crops. We have no proof that they are embolic in origin.

There is general agreement that a *leucocytosis*, at least of any considerable degree, is not a feature in these chronic cases. Indeed, the type of count is very apt to be round about 9000. In my second series of cases the actual figure averaged 9300. But a leucopenia is quite common. This contrasts markedly with the leucocyte count in the acute cases, in the second series of which the figure averaged 22,000.

The degree of *anæmia* varies much. It may be so great as to raise the question of pernicious anæmia, especially when a marked leucopenia is present. But the proportionate reduction in hæmoglobin seems to be invariably greater than the reduction in red cells. It is to be noted that some patients retain their blood, and especially their content of red cells, surprisingly well under treatment, especially if kept in the open air. I have seen an erythræmia in one well-marked case, but the hæmoglobin content was well below 100 per cent.

*Pallor of the skin* is a striking sign in the chronic cases, though if this be marked, and particularly if the curious tint of the complexion to which Libman has given the term café-au-lait be present, the case is generally of considerable standing. As in the case of the actual blood content, however, it is surprising how well some of these patients keep their complexion for a long time if treated in the open air.

### *Embolism.*

Next to the evidence of endocarditis, consideration of which I take later, embolism is undoubtedly the most constant of all the signs of the disease. It was recorded in 142 of my second series of 162 cases. The vessels affected were, in the order of frequency, those of the spleen (108 cases), the kidneys (98 cases), the brain (26 cases), and the arteries of the limbs (13 cases). To these situations must be added the retina and the skin. Embolism, or one of its sequels, is not infrequently the event which brings the patient under observation, and in many instances of apparently mysterious signs and symptoms it is this process which offers a satisfactory clue to the problem. Be it remembered that the size of the detached fragment of material may vary from something microscopic to something so large as to obstruct a vessel of considerable size.

1. The *spleen* is the most commonly affected of the internal organs. The more chronic the case the more common is it to find the spleen enlarged during life; indeed, it is probably correct to say that in chronic cases a palpable spleen is an invariable finding. Early in the disease, and when the organ is as yet not palpable, pains in the upper left quadrant of the belly, or hereabouts, are highly suggestive. These pains, associated with fever, and perhaps referred to the flank, are sometimes mistaken for pleurisy; when friction is present, as it may be, the error is difficult to avoid. But pleurisy may actually be present in addition. I have only once seen a pleurisy with effusion (which was aspirated) complicate splenic infarction. Although, as already mentioned, in some of the slow cases the size of the spleen may be very considerable, we must not conclude, from our knowledge of the great frequency of infarction in it, that this is the only factor in the enlargement. There is doubtless the general factor of toxæmia, and there is also the factor of anæmia. Unlike the spleen in acute septic endocarditis, the organ is generally quite firm, and the infected areas almost never suppurate; the nearest approach to this seen post mortem is some degree of grumous softening; even this is uncommon.

2. *Kidney.*—If we consider in connexion with this organ that the glomerular lesions which are so characteristic a feature are embolic in nature, a

they probably are, then it is likely that the kidney is affected by the embolic process quite as often as the spleen. The frequency of embolism here must not, as has often been pointed out, be judged only by the appearance of a hæmaturia; in many cases the number of red blood cells passed in the urine is so small as to call for microscopical search, and this should be undertaken very frequently. I have pointed out that a small hæmaturia may be missed, but a brief albuminuria consequent upon it may be detected; intermittent albuminuria should, therefore, suggest renal infarction just as intermittent hæmaturia does. The process of renal infarction is generally, but not always, painless. In one case under observation the renal emboli were accompanied by severe lumbar pain, so much so that calculus and tuberculosis were both suspected.

We owe especially to Gaskell and to Baehr our knowledge of the intimate changes in the kidney, only ascertainable by microscopical examination. These investigators described a form of glomerular change which they regard as peculiar, and to which Libman, in particular, has come to attach great significance. Indeed, according to the last-named observer, the discovery of the hyaline-like change in portions of the glomeruli which is the end stage in the Gaskell-Baehr type of nephritis enables us to say with confidence that an associated sclerotic heart-valve is the result of a "healed bacterial endocarditis." If this conclusion be borne out by other workers, and we may regard the lesion as almost a specific effect of septic endocarditis, its value in post-mortem interpretations will be very great.

3. *Brain.*—Cerebral embolism is by far the most serious of all the common events of this nature. It not infrequently brings a latent case very rudely into prominence; it often determines the fatal ending, and not seldom at a stage in the disease when, on all other counts, a hopeful period of quiescence has arrived in regard to the toxic process. Experiences like these it is which lead the physician to speak with caution even in the face of definite improvement in the general state, including quite lengthy periods of apyrexia. Death in this disease may be accidental and mechanical as well as the natural termination of an intractable toxæmia. The most common clinical result of cerebral embolism is hemiplegia, with aphasia if the hemiplegia be right-sided. Monoplegias are much less common. The resultant cerebral shock is usually considerable, and the outlook, even immediately, is grave. I have twice seen a second hemiplegia on the other side, the interval between the two attacks being in one case only three days, in the other case 12 months. The sequence, originally described by Douglas Powell, of hæmorrhage following the septic embolus, is common, as post-mortem experience shows, but acute cerebral softening, short of actual hæmorrhage, is perhaps quite as common a finding.

Irritative cerebral effects occur as well as paralytic, and these may sometimes be correlated post mortem with subarachnoid hæmorrhages. I found 10 such lesions recorded in 118 post-mortem examinations. In none of four cases in which choreiform movements were present was there, unfortunately, any opportunity for post-mortem examination.

4. Plugging of arteries in the *limbs* is probably more common than is thought. Unless the arteries be carefully examined a bout of pain and some swelling, say in the wrist and hand, or in the foot, is sometimes considered to be arthritic in nature, when it is really the result of embolism in the radial or one of the branches of the posterior tibial. That the arterial pulse is not often obstructed for long, and rarely completely obstructed, adds to the deception, since coldness of the part beyond the partial block, still less gangrene, does not occur. We must suppose that the absence of these last-named effects is due to the friability, not to say softness, of the embolus, allowing of rapid disintegration, or channelling or both. All this is in marked contrast with the results following embolism, if this takes place in (non-septic) mitral stenosis, when gangrene is not at all uncommon. A common sequel to these septic emboli in vessels in the limbs is *aneurysm*, the development of which helps to explain the absence of serious nutritional changes in the part supplied by the affected vessel.

I have twice seen *mesenteric embolism*. In one case there was an attack of abdominal pain, followed in three days by a swelling about the size of a golf ball and situate just to the right of the mesial line and a very little below the level of the navel. Despite the unusually discrete nature of the lump and its peculiar situation, the case would doubtless have been considered one of acute appendicitis had it not been that about the time of this occurrence the patient became suspect on the score of a possible septic endocarditis. A positive blood culture determined the diagnosis. In the other case a surgical colleague removed a small aneurysm from the right ulnar artery near its origin from the brachial. A routine digital examination of the rectum had discovered the presence of two small firm lumps, lying close together, and felt easily through the mucous membrane of the bowel. They were thought to be enlarged glands. A post-mortem examination later revealed the fact that these were healed aneurysms on the superior mesenteric artery. There was a third small aneurysm on the hepatic artery. Death had occurred from hæmorrhage into the cerebellum, no doubt secondary to another embolism in this situation. Aneurysm of the *ophthalmic artery* occurred in one of my cases and was observed conjointly with me by Foster Moore.

### *State of the Heart.*

The state of the heart in chronic septic endocarditis deserves a note. The salient feature, and one upon which there is general concurrence, is that it maintains its functional capacity in a very striking manner. Indeed, it may be said with truth that this is not a disease of the heart at all, but of the endocardium; hence my expression in my first lecture, "endocarditis vera." This fact contrasts markedly with the state of things seen in a rheumatic endocarditis, where, to a large extent, the converse applies. Many of the patients in the disease now under consideration enjoy complete cardiac sufficiency for months after they fall victims to their infection. This is no doubt the reason why so many of them do not come under our notice until long after the initial stage of the process is past. Soldiers remain in the firing line, doctors continue their arduous profession, farmers proceed with quite heavy labour, until one or other of the accidents of the disease leads them to report themselves. Even then it is often difficult to persuade them to consider themselves ill. This retention of cardiac efficiency, combined with that buoyancy and optimism which I have called "spes endocarditidis," renders these patients oft-times difficult to treat. A doctor, casually mentioning to his partner that he could not see the print on the extreme right side of his newspaper, submitted to a cursory examination; it was found that he had the cardiac signs of aortic incompetence and a retinal hæmorrhage; on fuller examination a diagnosis of septic endocarditis was not difficult. He refused treatment and carried on his work. A month later he attended a difficult confinement, using forceps. He woke the next morning to find himself hemiplegic, became comatose a week later, and died.

It is generally agreed that such evidences of heart failure as auricular fibrillation do not occur in these cases, another testimony to the same fact. This relative absence of myocardial involvement tends to persist to the last in many of the cases, though there is considerable divergence in the figures given by different authors as to the frequency of terminal heart failure. This divergence probably depends upon the fact that when small numbers of cases are dealt with the type of case which bulks most largely in the series from which the figures are calculated determines the figures. Taking my two series together, I found death with cardiac failure to occur in from 40 to 50 per cent. But both series contained a good many examples of the old rheumatic type of case. Yet in the groups which chiefly include ex-soldiers, death has been due to heart failure in much the same proportion as this; Cotton gives 47 per cent., and Starling gives 60 per cent., in their two series respectively.

Renal failure is admittedly the most frequent cause of death next to heart failure. After this, in probable order of frequency, come cerebral causes (and especially coma following embolus), exhaustion from the prolonged toxicity, and pneumonia.

# DIABETIC COMA WITHOUT ACETONURIA.

BY T. H. OLIVER, M.D. MANCH., M.R.C.P. LOND.,
HONORARY ASSISTANT PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

THE following case of diabetic coma possesses some unusual features.

A youth, aged 21, who had been on insulin treatment since May, 1923, and whose symptoms were so severe as to necessitate three injections of 15 units daily in order to keep the blood-sugar approximately normal and the urine free from sugar and acetone, developed a severe gastro-enteritis on Oct. 1st, 1925. As a result of this he was unable to take food and, owing to a misunderstanding, insulin was also withheld. On Oct. 4th he had very severe abdominal pain which suggested to his medical attendant the onset of peritonitis. He was sent from the country to Manchester, a distance of 80 miles, where I examined him about 5 o'clock the same evening. During the journey he became unconscious, and when I saw him he was in typical diabetic coma with a feeble pulse of 128 and a temperature of 98° F. The heart sounds were very feeble, and he appeared to be dying. A specimen of urine was loaded with sugar, but no acetone bodies were present. There was also a faint cloud of albumin. 40 units of insulin were given immediately, and afterwards 20 units every three hours throughout the night. Lemonade containing glucose was given in unlimited amount. By next morning the patient had partially recovered consciousness, but the pulse was still 120 and very feeble. During that day 80 oz. of urine were passed, sugar being present in all specimens, but no acetone bodies. From that time 20 units of insulin four-hourly were given, this being reduced gradually to 15 units t.i.d. as the patient improved. The trace of albumin persisted for three or four days and then disappeared. At the end of four days the glucose lemonade was discontinued and a solid diet gradually substituted. Except for one day, throughout the illness there were no acetone bodies present in the urine and, on that one occasion, only the slightest trace could be detected by ferric chloride solution.

The patient made an uninterrupted recovery, and when seen recently had resumed the diet of approximately 2100 calories and had returned to the dose of insulin which he was taking before his illness. The urine was sugar-free and the fasting blood-sugar was 0·19 per cent.

The features of interest in this case are: (1) The onset of coma heralded by acute abdominal pain simulating peritonitis. (2) The treatment with large doses of insulin, together with an unlimited supply of glucose solution. This prevented the onset of hypoglycæmia, and probably with the aid of insulin was helpful in repleting the glycogen stores and thus preventing complete cardiac muscle failure. As the sugar-tolerance after the illness was the same as before, the large amount of sugar given did not appear to have done any damage to the pancreas. (3) The almost entire absence of acetone bodies is an unusual feature in a case of coma. Such cases have been recorded, but this absence has been attributed to renal failure. In this case, however, not only was there no inability to excrete sugar-containing urine in large quantities during the first week, but even when recovery had occurred and the kidney function was then presumably normal there was no excretion of accumulated acetone bodies. Here at least it is difficult to believe that the direct causation of coma could be attributed to them.

# A STUDY OF SOME ASPECTS OF MINERS' NYSTAGMUS.

BY G. H. POOLEY, B.A. CAMB., F.R.C.S. ENG.,
OPHTHALMIC SURGEON TO THE ROYAL INFIRMARY, SHEFFIELD.

IN 1920 I was invited to become a member of the Miners' Nystagmus Research Committee of the Medical Research Council, and found it necessary to examine the whole of the existing evidence. There was a great deal of information, varying much in its value. Numerous papers had been published, and their contents accumulated without any very critical examination of the evidence contained in them. To get an insight into the conditions that prevailed it was necessary to read as much as possible of the writings of previous workers, to weigh the evidence as carefully and as dispassionately as possible, and to reinvestigate all the material which seemed of any real value.

Two different periods may be studied. The first ranges from 1870–1907, and the second from 1907 until the present time. In the epoch 1870–1907, Simeon Snell and Sir Josiah Court were the two principal writers in this country. In the evidence he gave before the Departmental Committee of 1907, Snell deals with the question of incapacity, his views being founded on over a thousand cases. He recognises a large incidence, but gives no statistics. In "Miners' Nystagmus," 1892, he deals with the result of examination of 134 cases, and dwells almost entirely on the causation. The evidence which Simeon Snell gave in the year 1907 may be epitomised as follows:—

> "Errors of refraction have no effect on miners' nystagmus. It is difficult to define which men of those who have marked oscillation are incapacitated; many are affected but not suffering. If miners' nystagmus is scheduled, a very large number of miners will seek compensation for slight amounts of miners' nystagmus, not severe enough to prevent them from working. It is very difficult to separate the genuine from the other cases. Probably a large proportion of miners will continue their work as they do now, and experience no pain or difficulty from the nystagmus; on the other hand, a large number of men who are able to do their work may seek compensation. Compensation will not be good from the men's point of view nor from the employers; it may throw so many men out of work and add enormously to the cost of coal-getting. A typical severe case of miners' nystagmus is fit for surface work in a few weeks, and fit for pit work eventually. I cannot remember ever meeting a miner who had given up work for nystagmus five or six years before and who had not resumed work below ground. I do not think a very great proportion of men are incapacitated by miners' nystagmus, only a small proportion; nor that it is a very great evil, but it may be considered so under compensation."

Sir Josiah Court, whose work has proved so remarkably accurate (1891), gives definite statistical information as to the incidence (see "Miners' Diseases"). In 1892 he examined the whole of the men, 735 in number, at two of the Stavely pits. Of these, 376 were actual coal-getters, of whom 45¾ per cent. had miners' nystagmus. Of stallmen in safety lamp pits generally he found about 40 per cent. had nystagmus, whereas of those in naked light pits only about 3 per cent. Sir Josiah Court in the same book (pp. 49 and 50) makes the following remark on incapacity:—

> "An Act of Parliament should be passed restricting the time for which compensation should be paid for miners' nystagmus to four months."

A careful study of the evidence given in 1907 brings many interesting details to light; for instance, it is interesting to read the evidence, medical and otherwise, given on behalf of the Lanarkshire Miners' Union, where, according to Dr. Freeland Fergus, miners' nystagmus now causes a lot of incapacity with loss of vision and other untoward results. Mr. R. Smillie, for the Lanarkshire Miners' Union, said:—

> "We have quite a number of miners' nystagmus cases in the 50 districts of Lanarkshire. Ophthalmic specialists

---

[1] Stallmen are both the coal-getters, or hewers, and the fillers, who fill tubs with coal in the working-place or stall.

advise men not to go underground again after miners' nystagmus, but men do go back and have no relapse."

Dr. Andrew Bell, for the Scottish Miners' Federation, said:—

> "Miners' nystagmus is a small thing, and does not incapacitate materially for the work of coal-mining; it may incapacitate for a week or so in the most severe cases. Compensation is usually asked for a week or two and should only be granted on expert evidence that the men cannot work. When a great deal of subjective distress is present with a slight degree of nystagmus, the severity of the subjective symptoms would be due to something else apart from the nystagmus."

In this he was supported by other witnesses called by the Scottish Miners' Federation, and also those of the Northumberland Miners' Federation.

### *Investigations Abroad.*

In France and Belgium, Dransart and Romiée were the principal early writers. Dransart, in 1877, gave an excellent description of the condition, on which it would be hard to improve even to-day. The physical signs were all carefully recorded, while of the symptoms he says:—

> "When walking on the roads below ground all objects dance, so that walking is difficult, like that of a drunken man. At the coal face sight is soon completely befogged, and the miner goes on striking without seeing clearly; it is habit not sight which guides his pick. He looks down; his sight then rapidly returns and he resumes his work for a time Then he has to rest himself again, and so on"

Dransart describes the effect of alcohol, and finds that errors of refraction are of no importance in the production of miners' nystagmus. In 1882 he had seen more cases, the bulk of which had good visual acuity—i e., 50 per cent. had 6/6 and a further 25 per cent. had 6/9. He says:—

> "Miners' nystagmus lasts as long as the man continues his professional work. When he stops he is cured in from six weeks to six months time."

In 1913 he wrote again, classifying miners' nystagmus into three groups—mild, moderate, and severe. Of all cases 90 per cent. were mild. In mild cases the oscillation is only obvious when looking up in daylight; in the moderate form oscillation is obvious when looking at about the horizontal level in daylight; in the severe, it is obvious when looking at or below the horizontal level in daylight, and is accompanied by functional trouble. The field of vision is undamaged, as is colour vision; the visual acuity, diminished when oscillation is taking place, recovers fully as soon as the eyes are still. Any disturbance of the general health, any accident, alcoholic excess, or fatigue, may change the mild form of miners' nystagmus into a moderate or severe form.

Incidence: By examining all the miners as they left their work he found that from 12 to 20 per cent., according to the light employed, of the miners in the north of France were affected by miners' nystagmus—that is, 15,000 were affected. Of these, not more than 50 in any one year had the disorder in a severe form. He records a case of a doctor who could produce oscillation like that of miners' nystagmus. He estimates the duration of incapacity from the mine as from two to six months in severe cases. Miners' nystagmus itself may last nearly the whole of a miner's working life, either in the mild form or with an intensity which varies from the mild to the severe form, to return to the mild again. He had watched some of the cases for 30 years. Miners' nystagmus in the mild form, 90 per cent. of all cases, is compatible with excellent general health and perfect fitness for work.

### *Work of Romiée.*

Romiée, of Liege, examined a very large number of miners in the years 1877–78, and again in 1892. His work was particularly good. He was the first to examine large numbers of men as they left the pit and get the percentage of those affected, noting the particular work on which they were engaged, and the light with which they were working. He was, I believe, the first observer to get the true incidence of the disorder. He also examined the same collieries and many of the same miners a second time after an interval of several years, and tested the incidence again so as to compare it with his previous findings. He notes that miners with squint are not unduly affected by miners' nystagmus. Fatigue increases the physical signs; a good sleep decreases them. Visual acuity is normal except when oscillation is very marked.

He tested the light given by safety lamps, noted the diminution of light due to coal-dust on the lamps, and the reduction of illumination at the working place due to the necessity of putting the safety lamp, so that it should not be broken, much further from the work face than the candle or naked light. He judged the severity of any attack by the degree of elevation of the visual regard at which the oscillation commenced in daylight. He says:—

> "In very rare and temporary cases, defective sight due to the oscillation may make it impossible for a miner to work, and this may recur from time to time, though this does not keep a miner long away from the coal face, even though his eyes remain much as they were. When a miner cannot do his own work, a temporary change to other work, either in the pit or on the surface, is an excellent means of stopping the discomfort and curing the nystagmus The giddiness is not dangerous and it does not make miners fall or break their safety lamps.
>
> "The condition of a nystagmic miner at work, despite the little inconveniences which he experiences, is much the same as that of any other miner. The affliction is so well tolerated, even in the most pronounced cases, that a miner cannot be persuaded to remain under treatment for nystagmus alone. An ailment which only furnishes a rare example to medical view unless searched for cannot be considered *serious*. Miners whose nystagmus has slightly improved after a spell of surface work return to work at the coal face, and do not experience a return of the discomfort which made them stop underground work."

Pechdo, in 1893, struck by the much greater incidence of miners' nystagmus in safety-lamp pits, particularly in some of them, than in naked-light pits, came to the conclusion that poisoning by coal gas was the cause of miners' nystagmus.

### *Modern Writers.*

Of the modern writers Stassen, Ohm, Llewellyn, and Robson deserve consideration.

During the years 1914–19 Stassen ("La Fatigue de l'Appareil Visuel") made a most comprehensive investigation of the conditions under which miners' nystagmus developed in Belgium mines. He examined the entire personnel of several different mines, including zinc and iron mines. He made exact notes of the class of work done by the men examined, the depth of the seams worked, the thickness of the seam, and of the lights employed. He gives details of the examination of 11,170 miners employed in 10 different safety lamp mines, of whom 7025 had been examined both at the commencement and at the end of a shift of work. This was in addition to 80 workers in iron mines, three of whom had miners' nystagmus; 40 workers in two zinc mines, four of whom had miners' nystagmus; and 76 workmen in a naked-light coal mine, of whom 16 had nystagmus. He gives all conceivable information, with carefully worked out statistics of more than 13,000 men examined, and discusses almost every possible aspect of the question with great minuteness. The book is a perfect mine of information and should be read by everyone before taking part in any discussion on the subject.

Coppez has written an able book on nystagmus in which he gives valuable information on the subject of dark adaptation Ohm, of Germany, has written a good deal, his views on the duration of incapacity caused by miners' nystagmus agree with the views of modern continental experts, such as Stassen and Coppez. Very few miners stop underground work for more than three months on account of miners' nystagmus in the Bochum district of Germany. As regards the causation of miners' nystagmus, he maintains that the eyes are normally in a state of rhythmical movement, controlled by various stimuli received by the retina. After exposure to defective light for a considerable time, these rhythmical movements become coarser and slower, and can be recognised as oscillation of the eyes. As a Tyndall research scholar, Llewellyn measured the amount of illumination which fell on the coal face, and so confirmed the work of Romiée; he has since written a well-known book on the subject. Robson has taken quite extensive extracts from the work of Marie Stopes on the "Chemistry of Coal," but has produced no evidence, experimental or otherwise, as to the toxic gas which causes miners' nystagmus. Such a gas may exist, but mere assertion is not proof.

*Home Office Statistics.*—These are published every year, and give the fullest information as to the number of successful claims for compensation and the duration of these claims. It is well to note that at the end of 1921 more than 600 miners in this country had been in receipt of compensation for five years, and 59 for more than ten years.

### *The Ascertained Facts.*

What data can we obtain from these writings? The actual incidence of miners' nystagmus, as obtained in the only scientific way by examination of all the miners engaged in different pits, was very much greater in safety-lamp pits than in naked-light pits, Sir Josiah Court's figures being corroborated by all the continental observers. Roughly, 50 per cent. of all actual coal-getters had gross oscillation of the eyes visible in daylight. How many more would have had traces of oscillation if examined in a dark room after exercises we can only guess; probably, judging from my own experience, the percentage would have been considerable.

The evidence is also conclusive that miners in old days seldom stopped work for miners' nystagmus, and then only for a few weeks, or very exceptionally months, during which they worked on the surface. We must remember that in the period 1870–1907 the working hours were much longer, and the safety lamps gave less light than those now in use. On the other hand, there were more naked-light pits at that time and the average depth of the pits was less, although the ventilation was certainly worse than it is now.

What are the conditions to-day? (1907–1925). We have no recent British statistics as to the actual incidence of miners' nystagmus under post-war conditions, and this, I hope, will shortly be rectified; but from what evidence there is, it would seem that the true incidence rate is, if anything, less than it was. There has been a marked increase in the percentage incidence of claims for compensation for incapacity due to miners' nystagmus. This rose from 0·05 in 1908 to 0·42 in 1922 in this country, though there has been no corresponding increase in Belgium, France, or Germany.

The facts which emerge are these. Miners' nystagmus is found both in naked-light and in safety-lamp pits, whether coal, iron, or zinc, the incidence being far greater in safety-lamp pits. This is due either to the diminished light of safety lamps, or to the poisonous effect of some ingredient in the gas which necessitates the use of the safety-lamp. The worse the illumination at the coal face the greater is the incidence of miners' nystagmus. In naked-light pits, or even in zinc mines, cases of miners' nystagmus do occur. The more gassy the pit, the dirtier are the lamps and the less is the light given by them. Conversely, the worse the light the greater the impurity of the air.

What is the toxic ingredient of the gas found in the pits? Is carbon monoxide—the most toxic—the cause? Prof. J. S. Haldane (first report, Miners' Nystagmus Committee) has shown that insects without hæmoglobin can live for a prolonged period in 80 per cent. carbon monoxide. Logan and Glaister report many more cases of carbon monoxide poisoning in workers in lime quarries, gas-engine shops, &c., than in miners, with whom it generally seems to be the result of fighting a gob fire. Nothing in the least like miners' nystagmus occurs in carbon monoxide poisoning, so it is improbable that carbon monoxide is the cause of miners' nystagmus.

Are there any other non-explosive toxic gases in coal, zinc, and iron mines which, when inhaled in small quantities for a lengthy period, cause miners' nystagmus? It may be that there are, though so far no evidence has been produced to show that such a gas exists or can cause anything even remotely resembling miners' nystagmus. Congenital nystagmus, labyrinthine nystagmus, and nystagmus due to cerebellar lesions we know. Encephalitis lethargica does give rise to a form of nystagmus not unlike miners' nystagmus.

The first task I set myself was to reinvestigate the question of the influence of errors of refraction on miners' nystagmus. For this purpose I examined just over 100 consecutive cases of miners as soon as possible after they had been certified to be incapacitated by miners' nystagmus. This, besides giving valuable evidence of the unimportance of errors of refraction in miners' nystagmus, also showed that there was a considerable variation in the severity of the attacks for which certificates of disablement were given. This necessitated an attempt to classify the severity of the attacks. That was my next task.

A visit to Strassen and Coppez in Belgium, and letters to Ohm in Germany, confirmed the opinion I had formed that in Belgium and Germany miners do not now stop away from work either on the surface or below ground nearly so long as the British miners do. I came to the conclusion that this was not because the incidence of miners' nystagmus is less severe in Belgium than it is here, but because the determination of the incapacity is entirely in independent medical hands in Belgium, and also because the work selected by the Government medical expert for each man is immediately available for him. Information received from Germany and France shows that miners' nystagmus is about as prevalent there as it is in Belgium, and that the duration of incapacity is much the same. The method of dealing with it is also very similar.

### *Summary.*

1. The actual incidence of miners' nystagmus among miners examined at work was the same, during the period 1870–1907, in France, Belgium, and Great Britain. 2. The incidence of incapacity due to it was also the same in this period, 1870–1907, in all these countries, and was very slight and of short duration. 3. Since then the claims for compensation for incapacity due to miners' nystagmus have increased, both in this country and on the continent; but in this country the number of new claims has increased very much more in proportion, and the duration of the period for which compensation for incapacity has been claimed is far greater in this country than in Belgium, France, or Germany. 4. In American coal-mines little is known or heard of miners' nystagmus, or of any incapacity being caused by it. 5. In this country there is a wide divergence in the severity of the miners' nystagmus for which compensation is claimed.[2] 6. By far the greater number of observers, particularly of those who have made an extensive examination of large numbers of men at work, are agreed that those miners are most affected who work in the poorest light, and they attribute the condition to working in defective light. 7. Prof. Haldane, who has an unrivalled experience of the conditions of coal-mining, declares that the incidence of carbon monoxide in coal-mines is not greater than it is in many large towns where coal is being burnt. Moreover, he has shown that carbon monoxide is not a tissue poison except from its effect on hæmoglobin.

The increase in the incidence of claims for compensation for miners' nystagmus, and of the duration of those claims as compared with that which prevailed in this country during the period 1870–1907, and prevails now on the continent, would seem to be due to claims for incapacity not being decided by a few picked medical experts as on the continent. As a result confusion has arisen between a condition due to miners' nystagmus and a condition which is the result of a subconscious desire for unearned pecuniary gain, which is found not only in miners suffering from nystagmus or injury to their eyes, but in many other claimants for compensation for injury to eyes, &c.; in members of the general public—e.g., "railway spine and shell shock"; and among those who claim to receive the Old Age Pension before they attain the age of 70, giving defective eyesight as their reason. The remedy is obvious.

---

[2] See second report, Miners' Nystagmus Committee, pp. 18–21.

Reinvestigation, so far as I have gone at present, confirms the views expressed by the earlier writers—Sir Josiah Court, Simeon Snell, Romiée, Dransart, and of the more recent ones—e.g., Stassen, Coppez, and Ohm—as to the physical signs of the disorder, the effect of errors of refraction and the amount of incapacity caused by it. Its cause I still regard as unsettled, the existing evidence is strongly in favour of its being a compensatory effort on the part of the central nervous system to overcome the effect of working in defective light.

### *Further Research.*

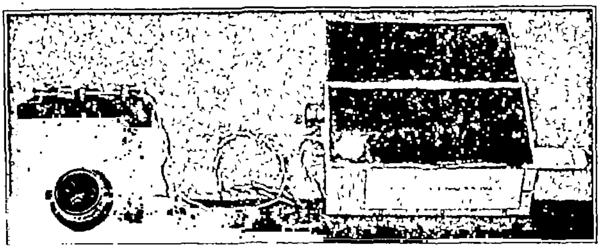
When these conclusions had been reached there were two factors which particularly invited fresh investigation. The first was the behaviour of the eye under conditions of dark adaptation; the second, for reinvestigation, was the incidence of miners' nystagmus in different pits under different conditions.

The first required a good deal of preliminary work. It is obvious to everyone that as daylight fails the differentiation of colours in a landscape, so infinitely varied in bright sunshine, becomes less and less marked until by moonlight everything is almost the same colour, and by starlight only the outline of objects can be detected in the shades of black and white.

After many experiments which failed to satisfy me I evolved the following scheme:—

I got a box about one foot long, lined its interior with black velvet, fixed a standard one-candle power lamp at one end of it (Fig. 1), and made an aperture at the other through which a slender beam of light could be projected across an otherwise absolutely dark room on to a black cloth covering a shelf on which test objects could be placed. The brightness of the illumination was checked by a luxometer (Edgcumbe and Everett) at the point of examination or at some known fraction of the distance in the case of feebler illuminations. Three observations were taken by each of two observers. The lamp in the luxometer and the lamp used to give the beam of light being exactly similar, it was easy to measure the light. For test objects I employed wooden cubes, 2, 4, and 6 cm., on which could be pasted paper of various colours, or black or white paper with the test letters of Snellens' type. The letters were spaced at measured intervals. To ensure that the test objects were at a uniform distance from the eye, I got a wooden frame made which was part of a circle with a radius of one foot, into which was set a straight piece like the spoke of a wheel, so that when the free end of the spoke was place against the observer's face just below the eye he was using, his eye was equidistant from each part of the circle (Fig. 2). It was covered with a black cloth when in use. I also had a slot fixed in the box which contained the lamp, so that dark glasses of various kinds could be fitted over the aperture in the box in such a way that the beam of light had to pass through them.

FIG. 1.



The apparatus used for projecting a beam of light.

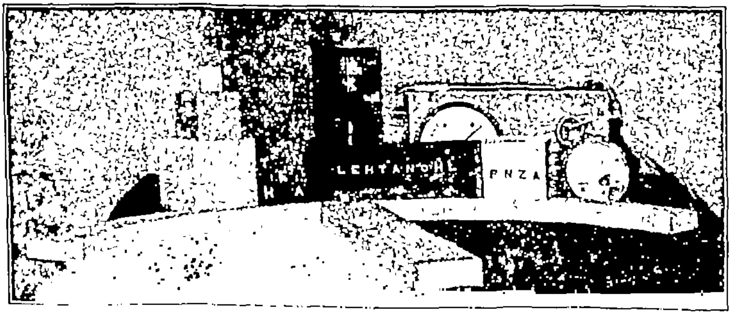
### *Experimental Results.*

By employing this apparatus I obtained the following results, taking the average of several readings by different observers, all of whom had been 30 minutes in a dark room before observations were made. With an illumination which varied from 4 candle-power to 0·0006 candle power:—

1. With 0·085 foot candle, Sn 0·6 was read at the centre or point of fixation and up to an angle of 1° from it; Sn 0·9 was read at the point of fixation and up to 2·5° from it; Sn 1·5 was read at fixation and up to 3·5° from it. The field of vision appeared to be evenly illuminated. Visual acuity was brightest in the centre of the field. This central area extends to from 1° to 1·5° from the fixation-point, and is surrounded by a zone in which the light flickers; this extends from the margin of the central zone for a distance of from 2° to 3° from the centre in different observers—i.e., the central zone has a radius which subtends an angle of 1° to 1·5°, and the second zone a breadth of 1° to 1·5° beyond it.

2. With 0·02 foot candle, colours—e.g., red, green, and blue—were easily seen, central fixation was easily maintained, and no flickering or fatigue was noticed. Sn 0·9 could be read at the point of fixation. Sn 1·5 at the point of fixation and up to an angle of 1·5° from this.

FIG. 2.



Test objects and wooden frame.

3. With 0·01 foot candle, a few letters of Sn 1·8 could be seen. Sn 2·1 could be read imperfectly, and Sn 2·6 read correctly. Two observers saw better at the point of fixation than elsewhere; the third observer better at a spot 4° from the centre. The legibility of type was greater at the centre and at 4° from the centre than elsewhere.

4. With 0·005 foot candle, Sn 3·6 could be read. One observer saw best at the point of fixation, one especially well *from the point of fixation to 4° from it.* The third saw best at 4° from the point of fixation.

5. With 0·0036 foot candle, Sn 4·8 and 3·6 were partly read by *all three observers, two of whom saw equally well* at the point of fixation and at 4° from it, while one saw better at 1° from the point of fixation on the temporal side than at *the point itself.*

6. With 0·002 foot candle, a central scotoma was clearly manifest; Sn 4 was read most clearly at 2° from the fixation-point, above, below, and to the inner side of it, and from 2° to 4° to 4½° on the temporal side of it. Central letters were just visible beyond 4½° on the temporal side, but not legible; at 10° letters were visible but only occasionally legible.

7. With 0·0012 foot candle, Sn 4·8 was read. Colours were just distinguishable, visual acuity was sharpest in a zone from 2° to 7° to the temporal side of the point of fixation. Colour vision, also form vision, soon faded as the test object *was moved beyond 7° from the centre.* Central fatigue was very marked; anything stared at became very indistinct; flickering was noted, shadows formed and crossed the visual field. Binocular vision was much better than monocular.

8. With 0·0006 foot candle there was a very definite central scotoma involving the whole central area with a radius of 5°. The centre and two adjacent letters of Sn 4 faded; next the whole field faded and then returned, including the central letters. This was followed by flickering, the central letter faded, and then the next two; they came back, but the central letter did not. When first a light of 0·0006 was turned on all the letters of Sn 4 were visible; a central scotoma formed in six seconds to two observers, and in 14 seconds to a third (an average of three observations each). The scotoma increased in size in 8, 12, and 23 seconds respectively to the three different observers. Letters became visible again in from 45 to 65 seconds; this was then followed by the stage of flickering and the reformation of the scotoma. In this test the letters subtended an angle of about 1°, they were white on a black background; red and green squares could be detected easily by simultaneous contrast. Fixation was hard to maintain.

9. With 0·0001 foot candle, a one-eyed man who had lost the sight of one eye in infancy was tried; *after adaptation for* 30 minutes, visual acuity was Sn 4; red was accurately distinguished, also green and yellow; visual acuity was most accurate at 5° and 12° on the temporal side of the point of fixation. The point of fixation faded, and the letters at 2° from the point of fixation faded even more quickly; he had a ring scotoma extending to 2° from the fixation-point. His field of vision extended to 20° on the temporal side and 10° on the nasal side. With him, as with other observers, there were two clear zones on the temporal side of fixation, the first at 5° to 7° from it, and the second at 12°, with a relative scotoma between them. With the one-eyed observer the letter C appeared to rotate clockwise in this dim light. Other observers noticed a movement of the letters which jumped in and out of the line. Flicker and fatigue were quite marked.

10. With 0·0006 foot candle, Sn 24 was read with binocular vision. One observer could distinguish red from green correctly by simultaneous contrast. The best visual acuity was at 5° on the temporal side of the point of fixation. Beyond 20° to 30°, even on the temporal side, a large white square subtending 8° was not seen. The central scotoma was very marked; moving objects were more distinctly seen than stationary ones; fatigue was very marked, and the observer's eyes were very uncomfortable.

Experiments were made by interrupting the main light and by flashing another light at an angle of about 40° to the line of visual regard. These caused a marked increase in the feeling of fatigue, but nothing else was observed. For comparison it may be noted that the light of the full moon was 0·05 by the photometer.

These experiments show that in very dim light there is a relative central scotoma with a ring of clear vision round it, with a restriction of the peripheral field of form vision. In addition to an increased difficulty in maintaining fixation, there is a tendency for fixed objects to move in a circle.

With 15 foot candle-power, Sn 0·3 was clearly legible; Sn 0·6 was clearly legible at the point of fixation and up to 3° *on the temporal side of fixation*; Sn 0·9 *was clearly legible* at the point of fixation and up to 4° of the temporal side of fixation; and Sn 1·5 was clearly legible at the point of *fixation* and up to 6° *on the temporal side of fixation.* 1 mm. squares of red and green could be clearly seen up to 7° or 8° respectively from the point of fixation.

The experiments were then repeated with the following results. With a reduction in the intensity of illumination :—

With 0·085 candle-power Sn 0·6 could be read and up to 1° from it; Sn 0·9 up to 2° from it; and Sn 1·5 up to 3° from it.

With this amount of light the visual field is fairly even; the centre is the best.

With 0·02 candle-power, Sn 1·5 was visible at the point of fixation, and up to 2½° from it. Central vision is the best.

With 0·01 candle-power, Sn 2·6 was read at the point of fixation and at 4° to the temporal side of it. In various observers these two points vary in intensity, being nearly equal. At 2° from the centre letters are not well seen.

With 0·005 candle-power, Sn 3·6 was read equally at the point of fixation, and at 4° on the temporal side of it.

With 0·0035 candle-power, Sn 4·8 was read rather better at 4° on the temporal side than at the point of fixation, but fairly evenly.

With 0·002 candle-power, Sn 4 was read most clearly at 2° *above, below, and to the inner side, and from* 2° to 4° on the temporal side. Central scotoma was quite marked. Letters beyond 4° visible, but not legible up to 10°. A letter was occasionally legible up to 10°.

### *Some Conclusions.*

These experiments show that the centre of the macula is the most sensitive spot for form and for *colour vision in bright light, but as the intensity* of the light diminishes the central area in the macula becomes both absolutely and relatively less sensitive to form vision than the area at the periphery of the macula and the adjacent part of the retina. The periphery of the retina appears to be relatively very insensitive to form vision, no matter what the intensity of the illumination may be, or whether the eye be light or dark adapted.

The threshold point of illumination at which the central area begins to lose its supremacy is between 0·003 candle-power and 0·002 candle-power. When the illumination is below 0·002 candle-power the scotoma is increasingly marked and the most sensitive part of the visual field is a signet ring-shaped area surrounding the macula at about an angle of 2° with an extension to 4° at the temporal side. The feebler the illumination the greater is the difficulty in maintaining strict fixation. The eye tends to travel in a small area all round the object it is fixing. This becomes exaggerated into something very like a vertical and even a rotatory nystagmus at times.

The arrangement of the different varieties of cones in the retina may account for the phenomena we have noticed. The following account, by Saltzmann, may be of assistance :—

> The central area of the macula contains very slender cones with an inner member 2·5 μ thick, irregularly arranged. These are found nowhere else. They are more slender than the other cones and might be taken for rods were it not for the absence of visual purple. Beyond this area the rods become more and more numerous and the cones wider apart, until some three or four circles of rods intervene between the two cones. This distribution is attained some 4 or 5 mm. from the centre of the fovea and is maintained quite constantly to the periphery. In the most extreme periphery the cones are again relatively increased. The foveal area, about 0·5 mm. in diameter, contains only cones. Towards the border of this area the cones are notably thicker and are *arranged in oblique rows.*

I am continuing my experiments on this subject, which I hope to elucidate *still* more fully. I am very much indebted to Dr. A. B. Nutt, for the very valuable assistance he has given me throughout this research, and also to Mr. Thompson, of Messrs. Theodore Hamblin, Ltd., for his valuable assistance with the apparatus.

I have not appended a bibliography. If this is required it will be found in the first report of the Miners' Nystagmus Committee. Some very interesting papers on dark adaptation by Selig Hecht have appeared in the *Journal of General Physiology.*

# A NEW DEVELOPMENT IN RADIUM THERAPY.

## THE APPLICATION OF THE LATER DISINTEGRATION PRODUCTS OF RADIUM TO THE TREATMENT OF CERTAIN SKIN CONDITIONS.

BY JOHN P. McHUTCHISON, M.A., B.Sc.,
PHYSICAL CHEMIST TO THE GLASGOW AND WEST OF SCOTLAND RADIUM COMMITTEE;
AND
W. HERBERT BROWN, M.D. GLASG.,
DERMATOLOGIST TO THE VICTORIA INFIRMARY, GLASGOW.

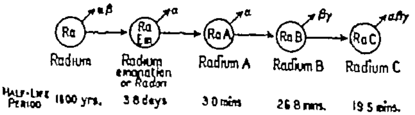
As indicated in a communication to THE LANCET,[1] we have been able to extend the usefulness of radium by employing it at a stage in its disintegration, at which hitherto it has not been applied to medical treatment. The particular *radio-elements* concerned have not previously been used therapeutically, and a definitely encouraging measure of success has attended their use in certain skin conditions. The discovery will be of special interest to radium institutes and other hospitals possessing radium, as it finds a permanent use for otherwise valueless products, and so extends the range of radium treatment.

It is usual to speak of the therapeutic effects of radium, but the actual element itself is of no value. Only when the radium breaks down do its special powers become apparent. The atoms of radium are constantly changing into other atoms, and a series of radio-elements is thereby brought into being. At each stage of the disintegration energy is evolved, and it is this energy which is employed in medical practice. The energy forms are three in number:—

1. *Alpha Rays* (α).—Fast moving atoms of helium.
2. *Beta Rays* (β).—Particles of negative electricity ejected from the disintegrating atom, with high velocities.
3. *Gamma Rays* (γ).—Non-material pulses in the ether, analogous to X rays, but of greater penetrative power.

All three kinds of rays possess definite powers of affecting the development and life of living cells, but the alpha rays have so slight penetration that they are of little or no therapeutic value, and as usually employed, radium owes its therapeutic powers to the beta and gamma rays. These are evolved during the third and fourth stages of the disintegration as shown in Fig. 1.

FIG. 1.

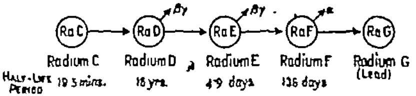


### *Active Deposit of Rapid Change.*

The radio-elements shown constitute the active deposit of rapid change and the longevity of the various elements is indicated by the time taken to decline to half. As generally used in medicine, the actual radio-elements *employed* are radium B and radium C, and the actual rays, the beta and gamma rays of these elements. This is true whether an active salt of radium is employed, or whether the emanation, the first disintegration product, is used. If a radium salt is used, an equilibrium is established among the various products, and owing to the long life of radium the strength of a radium plaque is, ordinarily [illegible] constant. But if a tube of emanation is the source of the activity, the tube gradually loses its power according as the emanation declines, and with it the radium B and radium C. Shortly after all the emanation in the tube has disintegrated, there is no radium B or radium C left, and therefore the tube has lost its strength. In radium institutes and hospitals *employing emanation* such *finished* emanation tubes have hitherto been of no medical use.

But it is well known that while radium C is the last member of the series to have powerful effects, the series does not end there. The subsequent elements constitute the active deposit of slow change and are shown in Fig. 2.

FIG. 2.



### *Active Deposit of Slow Change.*

It will be observed that radium D and radium E emit both beta and gamma rays, but unlike those from radium B and radium C, these are soft and possess little penetrative power. Hence, although after the decline of radium C in the emanation tubes, radium D and the subsequent elements grow up, the residual activity has not until now been considered of any value, and the finished emanation tubes therefore have been counted waste.

It occurred to one of us, however, that although the rays from radium D and radium E are feeble, yet if these radio-elements were concentrated from the finished emanation tubes, their activity might find use in medical treatment where deep penetration was not necessary, and owing to the long life of radium D supply a fairly lasting source of radiation. In particular it was thought that such a strong preparation of radium D and radium E in equilibrium might prove of value in the treatment of some superficial skin diseases. This conjecture has proved on investigation to be justified, and encouraging clinical results have been obtained.

Our

---

[1] THE LANCET, Feb. 9th, 1924; see also [illegible] 1924.

different sizes and shapes to suit different situations. They were thin enough—generally 0·2 to 0·4 mm.—to permit of slight moulding and adjustment to the skin surface. Most were of an oval shape, from 10 to 12 sq. cm. in area, and had the active matter present as sulphides along with lead (see "Preparation of Applicators" below). In fixing the active powder to the applicator the powder was uniformly distributed over the metal, then moistened with chloroform, and a very thin coating given of a celluloid varnish made up as follows: solution of celluloid in amyl acetate, ⅛ oz.; acetone, ¾ oz.; acetic acid, ¼ oz.; acetic ether, ⅛ oz. The active side of the applicator was covered with a layer of crêpe-de-chine to protect the active matter from contamination and from moisture. The applicator was then fixed over the affected area with zinc plaster, and the patient instructed to keep it perfectly dry.

In every case the applicator was removed after a decided erythematous reaction was produced, and, if necessary, applied to the same area in about four to six weeks time, after all trace of the previous reaction had disappeared. Occasionally slight blistering was produced, necessitating dressing the part with boric ointment. In one case a very marked crusted reaction was produced after 17 days' application. From our experience blistering should be avoided. Good results are likely to be obtained if the applicator is worn only long enough to produce a mild erythematous reaction.

### *Case Records and Results.*

CASE 1.—Miss M., aged 25. Port-wine nævus of the left cheek and chin, colour rather bright red. Five applications were given, but as this was one of the early cases treated the first two were tentative and were not of sufficient duration to produce the required reaction (Figs. 3 and 4). The actual facial appearance is even better than the photograph indicates.

CASE 2.—D. T., girl, aged 7. Extensive and somewhat patchy capillary nævus of right cheek, extending up to and over right eyebrow. The patchy portions were about the size of a threepenny piece, bright red in colour with well-defined spider nævi portions between. The skin on the areas treated became soft and white. Treatment in this case was done slowly and covered a period of two years, and the parents were very pleased with the result.

CASE 3.—Miss H., aged 16. A red capillary nævus of port-wine type over left jaw and cheek. Four applications were made. The condition has responded and shows much improvement, but the result has not been so striking as in the other cases owing to a mild degree of pigmentation resulting. One application in this case was overdone, producing a definite crusted reaction, which may account for the pigmentation.

CASE 4.—Baby L., aged 12 months. A circumscribed nævus of mixed type on abdomen; it had previously ulcerated in the centre, which accounts for a central scar present. The nævus was the size of a two-shilling piece, strawberry red in colour, and elevated above the skin by one-eighth of an inch. After two applications the nævus had completely flattened down and the colour faded to a faint bluish tinge. Slight pigmentation outside the area treated has in this case also followed a somewhat overlong exposure, but this it is expected will gradually disappear.

CASE 5.—Baby R., aged 6 months. A small capillary nævus on point of left shoulder, about size of a shilling, strawberry red colour, elevated above skin by one-sixteenth of an inch or more. With one application there was immediate improvement.

CASE 6.—Miss G., aged 28. Lupus erythematosus. This was an extensive chronic case involving a large area of forehead, nose, and part of one cheek. All precautions had been previously taken to eliminate any source of focal infection; septic tonsils had been removed and decayed teeth extracted many months before, without any apparent change. There was no evidence of tuberculosis. Treatment was confined to the patch on the forehead and to the cheek. Reaction to the treatment was marked, blistering being noticeable. The result is a very marked scarring over the central portions of the lesions, and this scarring has remained for over a year. Difficulty, however, was experienced in arresting the slow spread at the margin. The disease still remains active in parts, but there is apparently a definite arrest with marked scar formation over most of the treated portions.

We consider the results very encouraging. The parents of the infants all expressed themselves as greatly pleased with the results produced, and the adult cases were so satisfied with the improvement that they were most anxious to continue the treatment to include all the affected areas, in spite of the inconvenience of wearing the applicators on the face.

### *Extraction of Radium D and Radium E.*

As the result of some ten years' use of radium emanation by the Glasgow infirmaries and hospitals under the auspices of the Glasgow and West of Scotland Radium Committee, more than a kilogramme of finished emanation tubes of various shapes and sizes had been collected in the laboratory at Glasgow University. These tubes were the source of the radium D and E used in the research. The radium D and radium E, it will be understood, formed a sub-metallic deposit on the inside of the finished emanation tubes. Most of this deposit is soluble in fairly strong hydrochloric or nitric acid, but, possibly owing to the recoil and bombardment which had taken place inside the tubes during the disintegration, the active matter is slightly embedded in the glass and its solution is not easily effected. The following table shows the solvent power of various acids under different conditions.

*Solvent Action of Various Acids on Deposit of Radium D and Radium E in Emanation Tubes.*

| Acid. | Treatment. | Percentage strength dissolved out. |
|---|---|---|
| 50 % hydrochloric .. | Boiling for 5 hours. | 83·1 |
| | ,, 10 ,, | 83·4 |
| 50 % nitric .. .. | ,, 5 ,, | 82·9 |
| | ,, 10 ,, | 83·0 |
| Conc. hydrochloric .. | ,, 5 ,, | 82·0 |
| | ,, 10 ,, | 83·6 |
| Conc. nitric .. .. | ,, 5 ,, | 83·4 |
| | ,, 10 ,, | 83·4 |
| Aqua regia .. .. | In cold for 3 days. | 73·5 |
| | Boiling for 5 hours. | 86·8 |
| | ,, 10 ,, | 88·5 |
| | ,, 20 ,, | 90·4 |
| | ,, 40 ,, | 92·4 |

Aqua regia (4 parts of conc. hydrochloric acid to 1 part conc. nitric acid) is the best solvent to employ, and fairly prolonged boiling is necessary to effect the maximum solution. In none of the extractions was it possible to extract more than 93 per cent. of the activity, as judged by a beta ray electroscope. Experiments were made to determine if this residual 6 or 7 per cent. activity could be removed, and it was found that this could be done by shaking the tubes with dilute hydrofluoric acid, which, of course, would dissolve some of the glass. This showed that some of the active matter is actually in the glass; but the small quantity is not worth the effort required to obtain it.

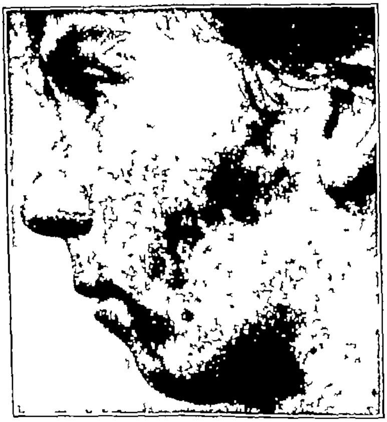
In extracting, therefore, it is recommended to use aqua regia, and to keep this at boiling point for a day or two on a sand bath. The tubes need only be broken, not powdered. Even on a sand bath very bad "bumping" will be experienced, and it was found necessary to employ a long upright condensing tube with ground-tapered end fitting into the ground end of the flask, and to clamp both firmly.

*Further Treatment.*—The strong acid solution is removed by decanting, and the tubes well washed with hot water, the washings being added to the extract. This is boiled down to quite small bulk, when an extra quantity of concentrated nitric acid is added, after which the solution is evaporated down on a water bath practically to dryness. Depending on the particular kind of applicator desired, as suggested below, this evaporation would be continued to as near dryness as is safely possible, with the subsequent addition of boiling water to any required dilution, or the slight acidity remaining would be neutralised with ammonia before diluting. It will be found convenient to handle about 40 or 50 g. of tubes at a time, and this quantity may be expected to furnish sufficient activity for four to eight applicators, according to what strength of these is desired.

### Preparation of Applicators

When the active matter is obtained in solution it is necessary to fix it in some way for medical application, since the quantity is so small that it cannot be handled by itself The most direct way is to associate it with some substance and apply this activated material to the diseased area, but, owing to the screening effect of this substance, some of the strength of the radium D and E is lost Therefore to make the most powerful applicators, radium D and E must be obtained alone and unassociated This may be done by taking the acid extract to perfect dryness in a platinum basin over a water bath, and most carefully dissolving off the invisible film with hot water, which gives a neutral solution containing nothing but radium D and E The quantity of this solution required to give the desired strength may be evaporated, portion by portion in the actual applicator, and the deposited matter protected by a thin film of collodion. By this method powerful applicators may be obtained, which will produce a reaction after only two or three days exposure

FIG 3



Port-wine nævus. Before treatment.

Such applicators have the disadvantage of containing no visible material and much of the active matter is apt to be worn off without attracting notice For these reasons it is suggested that the active matter in general should be associated with a quantity of some ordinary substance, so small as not to screen too much of the radiation, and yet sufficiently perceptible to permit safe handling of the applicators.

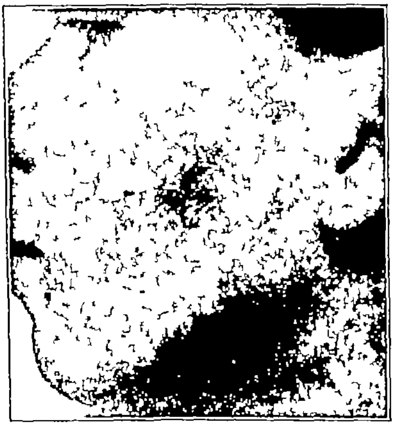
The methods that have been found successful are: (1) precipitation and adsorption methods, (2) electrolytic methods; (3) replacement methods In Nos (1) and (2) the active elements are associated with some finely divided material and an active powder thereby obtained which can be fixed with collodion on an applicator tray of suitable size and shape and this applied to the area to be treated No (3) involves the use of a metal plate which thereby becomes the applicator

1 *Precipitation and Adsorption Methods*

(a) If the original slightly acid solution is evaporated portion by portion on a nickel tray nickel nitrate is formed containing the active elements and this can be changed to the dry oxide by heating, or if the acid solution is neutralised with ammonia and the solution evaporated on the applicator, a deposit of activated ammonium nitrate is obtained

(b) *Sulphides* —The first attempts made were to precipitate the radio-elements along with lead sulphide by adding a lead salt (e g., lead nitrate) and precipitating with sulphuretted hydrogen gas and this method is recommended for the first trials of the new radiation It takes advantage of the chemical similarity between lead and radium D; radium E, which also forms an insoluble sulphide is precipitated at the same time To the extract of, say 30 g of tubes, about 0 5 g of lead nitrate is added and sulphuretted hydrogen passed through The quantity of lead nitrate added will be regulated according to the intensity desired, and if required the active powder can be diluted with ordinary lead sulphide Iron sulphide and mercuric sulphide precipitates may also be used to precipitate the radio-elements, but not copper sulphide One disadvantage of using salts of the heavy metals is their marked screening effect, and two lighter nuclear substances are therefore suggested

FIG 4



Same case as Fig 3. After treatment

(c) *Ferric Hydroxide.*—Very fine films of ferric hydroxide containing the radio-elements can be prepared by adding a small quantity of ferric chloride to the active solution precipitating with caustic soda, and drying in oven.

(d) *Calcium Carbonate* —Finely divided precipitated chalk, if shaken up for half an hour with the original acid solution after neutralising with ammonia and boiling off the excess, brings down about 80 per cent. of the activity by adsorption and makes a clean looking applicator (Of course a calcium solution may be used and sodium carbonate solution added )

This method has the very marked advantage that if the active powder on the applicator becomes damaged, it is sufficient to immerse it in dilute hydrochloric acid which puts the activated material into solution again, from which it can be extracted by any of the means suggested.

2 *Electrolytic Methods* —In the above methods the activated powder is spread on a tray and thus applied but if the surface to be treated is uneven it is practically impossible to ensure uniform distribution of the active powder Such uneven sites have arisen in cases of lupus erythematosus involving the nose, or nævus over an eyebrow or chin In such cases it is most suitable to prepare applicators by electrolysis of the active solution This suggests itself very naturally too, as a good means of fixing the active matter without employing any other material and, of course, an even deposit is easily obtained on any shape or size of applicator Owing to the fact that radium E (similar in chemical properties to bismuth) in acid

solution goes to the cathode, and radium D (similar to lead) in acid solution to the anode, it is not easy to extract both together. Therefore it is suggested that radium D should be plated out alone; from this radium E will grow, and in a month's time equilibrium will be established and a radium D and E deposit obtained, of practically constant strength for several years.

*Plating Out of Radium D.*—To plate as dioxide in acid solution requires the use of a platinum anode, and therefore it should be plated out as the element in strong caustic soda solution, using as cathode a nickel plate of required shape. To active solution add 10 c.cm. of 0·1 per cent. lead nitrate solution and make up to 150 c.cm. with strong caustic soda solution. Electrolyse for 24 hours at 70° C., using nickel cathode with 2 volts and a very small current, so as to obtain an adherent deposit. This can be protected with collodion or fine gauze if desired. The part of the electrode on which no deposit is wanted may be protected with wax or varnish.

3. *Replacement Methods.*—It remains to mention the extraction by chemical replacement, and this method has the advantage that no material is present to absorb any of the rays; but as a rule replacement methods are unsatisfactory, because while it is easy to deposit radium E on a metal plate by replacement, it is difficult to deposit radium D suitably; and it is radium D, which by its long life is the storehouse of the activity; without its presence radium E quickly declines.

Metals such as zinc and magnesium, which replace radium D from which radium E grows, or radium D and E together are readily affected by skin excretions and are therefore unsuitable as applicators. The only really suitable metal for replacement is nickel. A nickel plate (of the required shape and with the unwanted part protected with wax or varnish). when dipped in or boiled with a solution of radium D and E replaces only radium E, but this practically completely, and a very active plate is produced. But since no radium D is present the deposited activity due to radium E decays to half of its original value in five days to one-quarter in 10 days, to one-eighth in 15 days, and so on. But if the condition to be treated demands only a fairly short exposure the method is quite practicable. Iron also replaces radium E, but, of course, if an iron plate is left in the solution it rusts, and in the rust formed are found not only radium E, but also radium D by adsorption. This rust, of course, is a constant source of radiation and may be employed as in procipitation methods.

### *Strength of Applicators.*

The applicator most commonly used was an oval tray, ⅛ in. deep and 10 sq. cm. in area, and this caused the erythematous reaction to appear after 14 days' exposure; but it is obviously desirable to have some expression of its strength more definite than this reaction time. Unfortunately there is no convenient way of expressing the quantity of radium D and radium E present in the applicator, and in any case, if a carrier such as lead sulphide is used and the active film is protected with a collodion coating, there is a screening effect and some of the radiation is absorbed. For these reasons it is considered best to specify the strength of the finished applicator by reference to some easily reproducible standard, such as the alpha radiation from a uranium oxide film, as measured by an electroscope. The electroscope used was a beta-ray instrument made of brass, so mounted as to allow the applicator to be placed underneath, and with a screen of 1/10 mm. aluminium inserted in the base of the electroscope. The gold-leaf was 7 in. above the board on which the applicator was placed, and the circular base of the electroscope 4 in. in diameter was 4⅞ in. above the board. The uranium oxide tray was, of course, placed inside the electroscope, when its activity was being determined.

The activity of a 14-day applicator 10 sq. cm. in area, when measured through the 7 in. = 18 cm. of air and 1/10 mm. aluminium, was almost *five times* the activity of a circular uranium oxide film 4 cm. in diameter measured in the electroscope. If it is desired to produce the reaction after only three days' exposure over the same area the activity requires to be about 20 times that of the uranium standard.

The actual details of the *electroscope measurements* are:—

| | | |
|---|---|---|
| Natural leak of electroscope .. | = | 10 m. 30 sec. |
| 14-day applicator through 18 cm. of air and 1/10 mm. Al. .. .. .. | = | 4 sec. |
| 3 or 4-day applicator through 18 cm. of air and 1/10 mm. Al. .. .. | = | $1\text{–}1^{2}/_{5}$ sec. |
| 4 cm. diam. circular tray of uranium oxide inside electroscope .. .. | = | $18^{4}/_{5}$ sec. |

It will be remembered, of course, that it is the intensity that determines the reaction; a tray of 5 sq. cm. area, producing a leak, for example, of 5 seconds, will produce the reaction in seven days, as compared with a 5 seconds applicator over 10 sq. cm. It will also be understood that owing to the great difference in the penetrative quality of the rays emitted by radium D and E and uranium oxide, it is not possible to express one in terms of the other. But by using a standard film of uranium oxide for comparison, as indicated above, it will be possible to prepare applicators of suitable strength, after which the particular electroscope measurements (e.g., divisions of scale per minute per sq. cm.) may be used as standards.

### *Summary.*

1. The radio-elements, radium D and radium E, have been extracted from used radium emanation tubes, and in equilibrium together have been prepared for medical use in the form of applicators of different kinds.

2. Such applicators have been found to exert a beneficial action in the treatment of lupus erythematosus, and of various types of nævi. Conditions like eczema and psoriasis will also respond, but it has not been found convenient to treat large affected areas by means of applicators.

3. The radiation from radium D and radium E has the unique property so far as radium treatment of skin conditions is concerned, that it is all absorbed by the part being treated, since its effective penetration is only about 3 mm. of tissue.

4. Radium D and E applicators retain their strength and may be used for many years; 16 years elapse before the activity declines to one-half of its original value.

The authors desire to express their thanks to the Glasgow and West of Scotland Radium Committee for granting the facilities required in the carrying out of the research. They will be pleased to assist with further information or fuller details on any point if communications are addressed to Mr. McHutchison, Radiometric Laboratory, Glasgow University.

# ACUTE DILATATION OF THE STOMACH COMPLICATING ARTIFICIAL PNEUMOTHORAX.

By L. R. SHORE, M.B. CAMB., M.R.C.P.,
D.P.H. LOND.,
ASSISTANT PHYSICIAN, ROYAL CHEST HOSPITAL.

THIS case is recorded on account of the unusual mode of death of a patient undergoing artificial pneumothorax treatment for pulmonary tuberculosis. The occurrence of acute dilatation of the stomach does not seem to have been previously recorded in this connexion.

A woman, aged 32, was admitted to the Royal Chest Hospital on May 15th, 1923, complaining of malaise and cough of 18 months' duration. There had been loss of flesh since July, 1922. Sputum was scanty, contained tubercle bacilli; no hæmoptysis. The past history was of fair health; "bronchitis" in May, 1922, and "inflammation of the stomach" at the age of 21. There was no family history of tuberculosis.

*Condition on Examination.*—Very thin and pale; slight brown pigmentation of the face; fingers slightly clubbed. Physical signs in chest: In front. Heart not displaced.

Some limitation of movement of right upper chest, with flattening below and hollowing above the clavicle Impairment of percussion note over right upper chest down to fourth rib was marked A patch of bronchial breathing, with bronchophony and whispering pectoriloquy, was present in first intercostal space. There were crepitations down to fourth rib In back: Impaired percussion note, weakened air entry and crepitations down to the lower angle of the scapula on the right side At the left apex there were a few crepitations both in front and in the back. Other systems appeared normal.

*Treatment.*—Absolute rest. Temperature was swinging from normal to 100° F., with occasional rises to 101° or 102°. Pulse range was 100 to 120. Respiration-rate 28 to 40 Occasionally the sputum was slightly blood stained. The signs in the right lower lobe increased, and signs appeared at the apex of the left lower lobe In October there seemed to be a definite improvement which continued during November. Towards the end of November the temperature began to swing again and the signs to change. A large area of amphoric breathing, with hyper-resonance, appeared at the right apex. In the right lower lobe marked impairment of percussion note with crepitations appeared. X ray examination showed a localised pneumothorax at the right apex, and considerable disease of the right lower lobe The left lung seemed comparatively clear, and physical signs in this side had receded. Active disease at the right apex was shown by the spontaneous pneumothorax, and in the lower parts of the same lung by the spread of physical signs and the X ray findings.

Artificial pneumothorax was performed on the right side on Dec. 8th. Ten refills were given between Dec. 9th and Jan. 14th. The mean pressure was not raised above plus 2 inches of water, and the largest refill was 500 c.cm. of air The temperature was markedly reduced by the operation, and the general condition seemed to improve On Dec. 20th X ray examination showed good collapse of the right lung On Jan. 10th the patient vomited and complained of some abdominal pain No abnormal character of the vomit was noted. On the 11th the last refill was given, 400 c.cm. of air giving a final mean pressure of plus 3 inches of water On the 18th she complained of some dyspnœa and a choking sensation on lying down. There was no further vomiting, thirst, or suppression of urine. On the 20th the dyspnœa became extreme and she died.

*Post-mortem Examination* (Jan. 21st, 1924).—The body was of a small woman, thin and wasted; the abdominal wall was very tense. Thoracic cavity: Right lung collapsed, leaving a clear space from the thoracic wall of from 4 to 5 inches No fluid There were web-like adhesions at the right apex, a tough slender band at the junction of upper and middle lobes, also a mass of adhesions posterior to this. Left lung: Adhesions at the apex, otherwise clear Abdominal cavity: Enormously distended stomach.

Viscera: Right lung collapsed, not quite airless. Tuberculous cavities: (a) three in upper lobe, size of florin; (b) one in middle lobe, size of shilling; (c) one in lower lobe, 2 inches by 1½ inches Left lung engorged; some collapse at the base. No obstruction to bronchus or vessel found Scars on the surface of upper part of the lower lobe, and at the summit of the apex posteriorly Tuberculous cavities: (a) two in upper lobe, 2 inches by 1 inch; (b) one in apex of lower lobe deep to scar Liver slightly nutmeg Stomach: Precise measure of capacity not available; estimated at about 8 pints. Mucosa smooth, pyloric orifice not obstructed. Spleen, heart and pericardium, kidneys, duodenum, pancreas, biliary system intestine, pelvic organs: No abnormality found. Glands: Cervical slightly enlarged. Glands at bifurcation of the trachea, and paratracheal glands greatly enlarged, especially on the right side These glands were soft on section, but not caseous.

### *Discussion.*

The chief interest of this case lies in the mode of death As a point of minor interest, it may be remarked that the presence of a spontaneous pneumothorax at the right apex did not prevent effective collapse of the right lung The condition of acute dilatation of the stomach was first described by Hilton Fagge[1] in 1872 Cases have been recorded since by many observers, of whom Box and Wallace, and Campbell Thomson are conspicuous. Campbell Thomson[2] has collected 44 cases of this condition into a monograph; five of these cases are of his own experience. This writer has attempted a classification on the basis of pathological or clinical associations. Thus groups are defined in which acute dilatation of the stomach has appeared, and usually proved fatal, after gross dietetic errors, after injury, and after surgical operations. It is noteworthy that, in th cases following operations, those in the abdomin area do not constitute a majority. In one group ar cases in which no definite pathological lesion wa discovered. A fifth group contains cases of acut dilatation of the stomach associated with definit pathological lesion in the abdominal area or elsewhere or else associated with some clinical condition c ill-health The state of convalescence, or of debilit following prolonged ill-health, seems to precede th condition in a number of cases Two of the cases i Campbell Thomson's monograph were convalescent one from scarlet fever and another from a feve undiagnosed.

Box and Wallace[3] describe one case of acut dilatation of the stomach associated with diabeti coma. In the youngest case described, a child o 3 years, fatty degeneration of the heart, foun post mortem, implies former ill-health. Dietetic erro was also a factor Pregnancy occurs once in Campbel Thomson's collection, and has been described in lik connexion by the same observer elsewhere.[4]

### *Cases Recorded in Connexion with Intrathoracic Disease.*

Campbell Thomson quotes one case of empyema one of abscess of the lung, and three of pleurisy wit pneumonia. In one case with abscess of the lowe jaw purulent pericarditis was found post mortem Battle[5] records a case associated with pleurisy and pneumonia. H. H Brown[6] has described a case in which acute dilatation of the stomach terminated rheumatism and chorea. Mitral endocarditis was found post mortem. Box and Wallace[3] describe two post-operative cases in which acute dilatation supervened. In one was found tuberculosis of both lungs, and in the other suppurative pericarditis in association with osteoperiostitis of the femur.

It is impossible to estimate the proportion of cases in which intrathoracic disease precedes acute dilatation of the stomach. An incomplete survey of the literature, which included Campbell Thomson's book, and the cases recorded in THE LANCET between 1900 and 1924, revealed 60 cases Intrathoracic disease occurred ten times, the conditions recorded were: Empyema, abscess of the lung, tuberculosis of the lung, endocarditis of each one case; purulent pericarditis, two cases; pleurisy with pneumonia, four cases Campbell Thomson refers five cases to dietetic excess and four to injury In two of these cases only was the injury abdominal. In seven cases no other pathological lesion was found The cases with the associations of these three groups were found in Campbell Thomson's book; no other cases of the same sort were found in the literature examined The post-operative group seems to be the largest; 19 cases out of 60 belong here Of these, operations in the abdominal area accounted for nine. Several recoveries have been noted, but the condition has usually proved fatal, and has frequently been undiagnosed until autopsy, as was the case described in this paper.

In 37 cases the day of death after the onset of symptoms apparently attributable to acute dilatation of the stomach has been noted Thus First day, 7 deaths; second, 13; third, 8; fourth, 4; fifth, 4, sixth, 1. Occasionally the acute dilatation has seemed to exist with remissions for as long as 11 days prior to death The case here described died on what was apparently the third day.

Attention is directed to the fact that intrathoracic disease accounts for a considerable proportion of cases of acute dilatation of the stomach This proportion seems to be about half as many as the cases preceded by operation, but greater than those precipitated by injury, dietetic excess per se, or those without discoverable causation.

# THE CENTRAL NERVOUS DISTURBANCE MANIFESTED BY AN EPILEPTIC FIT.

BY J. P. MARTIN, M.D. BELF., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE NATIONAL HOSPITAL, QUEEN-SQUARE.

SINCE the experiments of Ferrier and the clinical studies of Hughlings Jackson, it has been considered that the epileptic fit resulted from a stimulation of the cerebral cortex; that there was on the brain surface of every sufferer from fits a hyper-excitable area in which an abnormal stimulus originated, and from which it rapidly spread over the whole cortex, causing a sudden discharge of all the cortical cells; that the movements of the convulsion were the effect of the discharge of the motor cortical cells, while the "aura" (if any) indicated the site of the hyper-irritable focus in which the stimulus arose. These views of Hughlings Jackson still dominate all writings on the nature of epilepsy. Gowers, though he accepted Hughlings Jackson's views, considered also the possibility that the fit was brought about by inhibition of the brain cortex, and this view has, I understand, been put forward recently in France by Hartenberg. If, therefore, we endeavour to form any clear idea of the main symptom of epilepsy we must examine the elements of the fit in their relation to these two theories.

Neglecting for a moment *petit mal*, fits may be full or partial (Jacksonian); but since the Jacksonian fit hardly ever occurs in idiopathic epilepsy, it is only with the former kind of convulsion that we are now directly concerned.

*The Full Fit.*—The epileptic attack has been often and minutely described. In its typical form it consists of two stages, the tonic and the clonic, to which may be added in certain patients a short preliminary stage, the "aura," and a post-epileptic stage of unconscious action, well called "automatism."

In a number of patients the approach of fits is indicated to the relatives or even to the patients themselves by certain prodromal symptoms—usually of a psychical nature. They consist of an apathy, a mental dullness, a loss of memory, sometimes a decrease of those qualities which we class as "refinement." These mental changes appear to indicate a decrease of the normal cortical activity or control. There is never a state of elation or "flight of ideas" or an increase of mental power such as we might expect from commencing excitation of the psychical cortex. It may, in fact, be taken as a general rule that an epileptic will not have a fit during a period of intense mental activity or of enthusiasm. The prodroma rather favour the theory of cortical inhibition.

Loss of consciousness is an essential element of the true epileptic fit; it is difficult to reconcile it with the theory of cortical excitatition, but of the theory of cortical inhibition it is an essential part.

In most patients the fit begins with the so-called "tonic" stage; with a complete loss of consciousness, all the muscles of the face and limbs and trunk are thrown into tonic rigidity. It has been shown by Cobb from electromyograms of convulsed animals that this rigidity of the muscles is due to a tetanus and not to an excess of postural tone such as causes the stiffness of hemiplegia and other spastic states. The "tonic" (i.e., tetanic) stage of a convulsion may be produced in an animal by strong electrical stimulation of the cerebral cortex. But, on the other hand, fits with the "tonic" stage as their major part may occur in very young infants in whom the pyramidal tracts are still unmyelinated and whose motor cortex is, for that reason, presumably functionless; there is nothing to suggest that the mechanism of the seizure is different later in life, and so we must suppose that this portion of the fit is, as in the infant, independent of the motor cortex.

The next and usually longer stage of the fit, the clonic stage, involves movements which, though subject to some individual variation, are very constant in type. They consist in rapid flexion and extension at the elbows, wrists (less), and fingers, and, in the lower limbs, of large flexion and extension movements occurring alternately in the limbs so that one lower limb is in extension while the other is in flexion; there are in addition upward and downward movements of the lower jaw, clonic retraction of the cheek, and in many cases contraction of the vesical and sometimes rectal musculature. All these movements are at first strongly damped by the tetanus of the muscles involved and their amplitude increases greatly as that condition passes off. Similar movements can be elicited by electrical stimulation of the cerebral cortex, and it was because of this fact that Jackson's theory of convulsions gained general acceptance. Another explanation of the movements of the clonic stage based on later work may, however, be presented. The movements of the limbs are exactly those which can be produced by spinal reflexes. The movement which the legs repeat —withdrawal of the one and extension of the other— represents the full response to stimulation of the sole of the foot in a paraplegic subject or in a decerebrate animal, what Sherrington has called the "walking" reflex. This reflex can only be elicited when the cortical control over the spinal centres is removed. The movements of the arms, if they reach their full amplitude, show not only flexion and extension but also, with the extension of elbow and wrist, an element of hyper-pronation or inversion of the forearm and hand, and correspond closely with those (first described by Buzzard and Riddoch) which result from painful stimulation of the axilla in cases of quadriplegia and some cases of hemiplegia. These latter are brought about by a spinal reflex and are only demonstrable when the cortical control of the arm centres in the spinal cord is cut off. The movements of the limbs which the clonic stage of the fit exhibits are therefore capable of being produced by centres which exist in the spinal cord. No reflex has to my knowledge been described provoking the masticatory movements of the jaws and the retraction of the cheeks which occur in the fit; but these elemental movements are present in animals deprived of their cerebral cortex and almost certainly represent a function of the medulla oblongata. It is, consequently, unnecessary, that in order to explain the clonic stage of the fit, we should invoke cortical activity.

If the plantar reflex be tested immediately after a fit it is usually of the extensor type—a further indication that cortical motor control is in abeyance. It has been suggested that this is due to exhaustion of the cortical cells as a result of their discharge, but the fact that a second and equally strong fit may occur within a few minutes seems to me to preclude that explanation; so quick a recovery of the cortical cells is unlikely, and it is much simpler to regard the extensor plantar response as merely one sign of an absence of cortical function which obtains throughout the fit.

The aura which occurs in a small proportion of patients was regarded by Hughlings Jackson as an indication of the area of the cortex in which the excitation began. But it is hardly likely that simple subjective phenomena such as flashes of light or noises in the ears are cortical in origin. There are, however, in a few patients, auræ, particularly visual auræ, of a highly developed kind. One of my patients always at the beginning of a fit sees a brick wall which heaves towards and away from him, coming nearer at each heave till at last it strikes him, and as it does so he loses consciousness. Such phenomena are probably allied to dreams; in any case it is difficult, in the face of other evidence, to accept them as any proof of cortical over-activity.

Post-epileptic "automatism" presumably represents an imperfect recovery from the fit, the motor functions having recovered and the psychic being still partially in abeyance. We may suppose either that the psychic cortex is still affected by a primary inhibiting influence or that it is suffering from exhaustion. If the former be the correct explanation, the mental state is possibly similar to that of a dream, and "automatism" in many ways on a parallel with somnambulism

These are all the elements of the fit, but another point that must be referred to is the constancy of the seizure. Though there are some variations, the elements of the attack are the same and their sequence is the same in nearly all cases. To such a degree is this true that provided there are no signs of organic nervous disease we base our diagnosis almost entirely on the description or observation of the fit. I have already referred to the constancy of the composing elements—the "tonic" stage and the stereotyped movements of the clonic stage. Constancy of sequence is found not only in the main divisions of the convulsion but even in small details; though the epileptic's hand may take up its posture in a moment at the onset of the fit, yet the thumb is always turned into the palm and the fingers closed over it. If the seizure were the consequence of cortical stimulation the movements would seldom occur in the same order in any two patients; their sequence would depend on the direction from which the stimulus approached the motor cortical area and the direction in which it spread over it, and no small movements such as those of the thumb and fingers could be so uniform in their order of occurrence as to produce a sign of value for differential diagnosis.

Thus in analysing the full epileptic fit I have not found any unequivocal evidence of cortical stimulation, but, on the contrary, in the prodromal symptoms, in the unconsciousness, and in the presence of an extensor plantar response at the end of the clonic stage I see indications of cortical inhibition, the movements of the clonic stage may be explained either by cortical or by brain-stem and spinal action, but the latter explanation is much more in accordance with the other elements of the fit.

I have not overlooked the fact that movements similar to those of a fit are caused by experimental stimulation of the brain surface. We must remember that in such experiments the cortical motor cells merely pass on the stimulus to the spinal and brain-stem cells, which are the true motor cells; and generalised convulsions with the same tonic and clonic stages can be produced in animals in which the cerebral hemispheres have been separated from the brain-stem and cord Their occurrence in infants has already been mentioned.

*Petit Mal*—A large proportion of epileptics suffer from minor as well as major attacks. The former usually consists of a momentary unconsciousness, interruption of speech, and loss of the continuity of thought, in many cases the patient suddenly falls down but is able to rise again at once These phenomena we cannot interpret as evidence of cortical stimulation, but rather of inhibition, of the speech, psychical and motor functions of the brain

*Conclusion*—We are forced to the conclusion that the essential central nervous disturbance produced by true (idiopathic) epilepsy is an inhibition of the cortical function and that in the major seizure this is accompanied by an uncontrolled discharge of centres in the brain stem and spinal cord.

### A Note on the Partial Fit.

The partial (Jacksonian) fit is very rarely, if ever, a manifestation of idiopathic epilepsy, but indicates a localised lesion of the brain and is therefore better called "focal" or "epileptiform." I only mention it here because it may be considered to have a bearing in the causation of the full fit.

In the partial fit there is no loss of consciousness, so that the chief indication of cortical inhibition is absent, and we must be guided by other features (1) When in association with a Jacksonian fit—say an attack of convulsive movements of the right hand—speech is affected, it is always in the direction of a loss of function; usually the patient becomes either quite unable to speak or unable to produce exactly those words which he wishes to use, both during the attack and for several minutes afterwards. (2) The movements of the partial fit are the same flexion and extension movements of the fingers or other parts that occur in the full epileptic fit; they are not complex or highly integrated movements such as we might expect from cortical activity; by the nature of the movements the attack declares itself as part of a full fit. (3) The conditions which produce such attacks are cerebral tumour (including abscess, gumma or tuberculoma), infantile hemiplegia, meningitis, and many other conditions in which the cerebral cortex is damaged. In practically all such conditions localised destruction of the brain is present. This is especially noticeable in infantile hemiplegia, a disease in which the motor cortex of the affected side is functionless, and at post-mortem examination shows atrophic sclerosis or porencephaly. Yet in such cases the fits may be confined to the limbs corresponding to that side of the brain

There are thus indications that the partial fit occurs when the function of a circumscribed area of cerebral cortex is impaired It is quite evidently not due to any increase of the normal function of the cells of the affected area, but whether it is in any way dependent on abnormal stimuli transmitted to the impaired cells and conducted by their fibres to the lower centres, or is merely an escape of the lower centres from cortical control, cannot yet be decided.

# PNEUMOCOCCAL MENINGITIS.

By V. M. SYNGE, M.D., D.P.H. Dub.,
F.R.C.P. Irel.,
VISITING PHYSICIAN TO THE ROYAL CITY OF DUBLIN HOSPITAL.

Owing to the comparative rarity of recovery in pneumococcal meningitis it may be of interest to record the following case, which was under my care and that of Mr Seton Pringle.

A boy, aged 16, was admitted to hospital on Dec 19th, 1924 He had received a kick from a horse 12 hours previously There was a depressed fracture on the left side of the bridge of the nose, and an incised wound two inches long above the right ear

*Condition on Admission*—The boy was in a collapsed state, complained of severe headache, and could not see with the left eye; pulse, 90, temperature, 98.8° F; respiration, 26 The knee-jerks and Achilles jerks were absent. The following day he was in an excited condition, uttering loud cries and shrieks even when undisturbed, the head was retracted, Kernig's sign present, extensor plantar reflex in right foot; temperature, 102°; pulse, 90 A lumbar puncture was performed on Dec. 21st, and 20 c.cm. of very turbid fluid under tension removed The fluid on standing gave a very copious deposit of pus and on culture Prof. J W Bigger obtained a pure growth of pneumococcus, Group IV For some days the boy remained in a heavy sleepy condition, with a spiky temperature rising to 103°; pulse, 90 to 100 Then the condition gradually improved, the temperature reached normal on Jan. 11th, 1925, all stiffness of neck and Kernig's sign had disappeared by Feb 6th and the knee-jerks were present but feeble. The pulse was rapid (90 to 100) until Feb 20th when it became normal. On March 6th the boy left hospital feeling perfectly well, the only abnormalities being the depressed fracture of the nose, feeble knee-jerks, and slight defect of vision of the left eye due to several now healed chorioidal ruptures. When last heard of, some months afterwards, he was in excellent health.

*Treatment* consisted in lumbar puncture repeated at intervals of three or four days, 20 to 10 c.cm. being removed at a time Five punctures in all were done, the last specimen of fluid being perfectly clear, but still under somewhat increased tension. Hypodermic injections of an autogenous pneumococcal vaccine were also given. There was a marked improvement after each lumbar puncture, and usually a fall in temperature after each injection of vaccine In this case infection had evidently occurred from the nasal cavities owing to fracture of the cribriform plate.

The first case of recovery in pneumococcal meningitis was reported by Jemma[1] in 1890. In a general review of the prognosis of pneumococcal meningitis by Rolly[2] in 1911 he recorded four cases of recovery out of 30 cases which came under his care. He states that up to that time only seven cases of recovery had been recorded. Two of his cases of recovery occurred in young adults and two in children. In all four cases there was coexistent lobar pneumonia, and the cerebro-spinal fluid contained a large amount of pus and numerous pneumococci. He treated all by repeated lumbar puncture; in one case—a child aged 2¾ years—he performed no less than 16 punctures and withdrew a total of 600 c.cm. of fluid. In a more recent publication[3] statistics are given of 7 per cent. recoveries in a series of 42 cases, and in another series there were 10 per cent. recoveries in 60 cases. Numerous other cases of recovery have been reported in the last few years. In some of these repeated lumbar puncture was the only treatment, in others serum was given in addition, whilst in others again fixation abscess was employed in addition to lumbar puncture and serum. Recovery may take place whether the patient is an adult or a child, whether the meningitis is serous or purulent, whether infection of the meninges is associated with pneumococcal infection of the lungs, or whether it is secondary to fractures of the skull with resulting infection from the nasal cavities, or whether it is a sequel to suppuration in the middle ear or accessory nasal sinuses.

[1] Baumgarten's Jahresberichte 1890

[2] Deutsch. Med. Wochenschrift, 1911, p 774

It is significant that in the case which I record the pneumococcus belonged to Group IV., though I have seen a fatal case in which the pneumococcus was also Group IV. The reported cases of recovery do not state the type of pneumococcus sufficiently often to enable one to draw any conclusion as to whether the type influences the prognosis materially.

*Résumé.*—1. A case of meningitis due to pneumococcus, Group IV., with recovery, is reported. 2. In pneumococcal meningitis recovery occurs in 10 per cent. of cases. 3. The essential treatment is repeated lumbar puncture.

## MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society was held on March 26th, Dr. WILFRID FOX, the President, occupying the chair, when a discussion on

### MARRIAGE AND SYPHILIS

was opened by Dr. G. RIDDOCH. In agreeing to open the debate, said Dr. Riddoch, he felt he was in a false position, as he was profoundly ignorant on the question of the infectivity of syphilis for, as a neurologist, he saw only the late effects, the tragedies. He would therefore use the opportunity to stir up a few warnings against giving too optimistic a forecast in the early stages of the disease. A perusal of the literature seemed to indicate that it was a subject on which no one was very well informed, yet it was of the first importance. There was now available much more precise information by which to answer the question so often put to the medical man by patients distressed in this way; at the present time it was a matter more for discussion than for dogmatic statement.

The first question was: How long, and under what circumstances, was syphilis infectious? It was agreed that in the primary and the early secondary stages —i.e., when the chancre was present and when cutaneous lesions appeared—the infectivity of the disease was very high; spirochætes were present in the semen and other secretions. It was when the later phases of the disease were considered that difficulties arose. The infectivity tended to diminish as the disease progressed, though not in a steady way; there seemed to be re-animations as shown in fluctuations in virility. Decision was difficult when the cutaneous lesions had disappeared and latent syphilis was present, the only manifestation being a positive Wassermann. When that was the case and the primary infection had taken place five or six years earlier, what was the infectivity? Clinical and experimental evidence seemed to show that infectivity was still present at this stage. In rabbits experimentally treated at such a stage the intra-testicular secretions and the blood were positive. Certainly spirochætes tended to persist for a considerable time in healed chancres, and monkeys could be infected with syphilis by injecting material from chancres which had healed 14 months, even though local and general antisyphilitic measures had been adopted. It was not known in what proportion the disease was infectious at this stage. What was the position when the Wassermann was negative? Could it be said that at this stage infection could not occur? He did not think so, especially when the Wassermann had previously been positive. Men who had so-called latent syphilis and, having been assured it was safe to marry had done so, had infected their wives, and the latter had borne syphilitic children. It was very desirable to know in what proportion of cases such an accident was liable to occur. In the late stage of latent syphilis—i.e., in the first four or five years after the infection, with or without treatment, and the Wassermann positive but without clinical manifestations—could it be definitely stated that there was no liability to the man, if he married, transmitting the disease to the offspring? He thought not, for the positive Wassermann showed that organisms of syphilis were still present in the body, possibly shut off in a gumma or otherwise isolated, but liable to be liberated into the system. Of six men infected three to six years previously who married while having latent syphilis, five of the wives developed a positive Wassermann, and four of them bore syphilitic children. To what extent were these exceptional occurrences? Clearly those cases constituted a warning. Were cases who admittedly had had a chancre, but whose Wassermann had remained negative for some time, free from infectivity? He did not know, and had not been able to find evidence that there was definite information on the point. There remained to be considered those late cases of syphilis with clinical signs, cases which were often seen because of neuro-syphilis. Were these cases, even with a negative Wassermann, certainly non-infectious? When a patient had got tabes or aortitis, or a gumma of the liver, he did not know whether infection was possible, but thought probably not.

In regard to infectivity, he thought the case of the woman was somewhat different from that of the man, especially in regard to syphilis in the secondary stage before treatment, for with her the danger of infection was greater than in the male. Colonel Harrison's view, with which he was in general agreement, was that the patient should be required to wait four years before considering marriage, and that this period could be shortened by treatment, if it were efficient and thorough, and that before suspending treatment the blood and cerebro-spinal fluid should be Wassermann-negative. Afterwards there should be an examination every month for a year, and a week after a provocative dose of N.A.B.; also at the end of another six months and after a year following a provocative dose. Coming well out of that ordeal seemed to justify marriage, but the speaker thought it might not be safe even then, unless the case had been caught early and the treatment commenced forthwith. Abrahams considered that if the cerebro-spinal fluid was positive, even without nervous signs, in the third year, the patient was a possible candidate for neuro-syphilis later on. That statement was made without much supporting evidence, but the question of how risky marriage would be in such a case was one well worth consideration. Another authority considered that a negative clinical and serological examination after seven years meant that the patient was reasonably safe, but that even then some cases showed there were exceptions. Prosser White considered that in the tertiary stage the local lesions were non-infectious, but the speaker had his doubts as to that. The question appeared to be even more difficult in the case of women, who seemed much more likely to pass the disease on to their progeny. One authority declared that a woman whose blood gave a positive Wassermann should never marry. Dr. Panton would probably say what was the significance of the Wassermann reaction, because in this matter the pathologist was a very important person. Often one saw patients who had been efficiently treated without showing clinical manifestations, or in whom, accidentally, the Wassermann was found to be positive. What was the infectivity here? He always felt unsafe about such cases. And could a man who had had a positive Wassermann but was now negative be pronounced cured and free from infection? The danger was that he was liable to become positive later on.

It was not sufficient, said Dr. Riddoch, to be able to answer the patient's question as to whether or not he was infectious and liable to transmit the disease; there was the further question whether the disease was likely to incapacitate him as a wage-earner later on, say 15 years hence. It was a difficult problem, but he knew of cases in which a favourable answer had been given by the medical man with disastrous consequences. In forming an opinion he stressed a thorough clinical examination of the patient, mentioning the case of a man aged 35 who had a chancre 12 years previously. He had mercury treatment—not very efficiently—and six years later had N.A.B. injections, and three years prior to marriage had N.A.B., mercury and iodide of potassium. But his blood was Wassermann-positive. Three separate syphilologists assured him it was safe for him to marry. Three months after marriage the speaker saw him and found him the subject of marked tabes, and the history showed that for years he had had lightning pains and had a habit of wetting the bed, this in addition to the pupillary and other classical signs of the disease. His view was that a positive Wassermann indicated the presence still of active spirochætes in the body, hence the prognosis given in such cases should be cautious. A great safeguard against error was not to be content with a single Wassermann test. A smaller proportion would show a negative Wassermann in the spinal fluid than in the blood. On the other hand, an ultra-cautious attitude was liable to breed syphilophobia. Stated in a broad way, his own feeling was that if a man had had syphilis and it had become generalised he ought to have treatment for the remainder of his life, otherwise he could not be said to be free from infectivity nor from the risk of remote complications. A more lenient view was justifiable in the case of a man who had never had a positive Wassermann in either the blood or the cerebro-spinal fluid. Finally, Dr. Riddoch raised the question of the fate of the offspring of syphilitic parents who were supposed to have been cured before marriage; also as to the treatment which could be considered safe and efficient to ensure that the patient would not develop later sequelæ.

### *The Pathological Aspect.*

Dr. P. N. PANTON said he could do little more than propound questions to which he was unable to find the answers. First, could it ever be said that a person who had had syphilis was cured? The information given by the blood Wassermann was insufficient evidence of cure, for that reaction might be negative for a time and then revert to positive. He did not think there existed any method by which it could be said that a person who had had the disease was certainly cured, though a possible exception was the patient with a chancre and a negative Wassermann who was strenuously treated from the first, coupled with—what he regarded as very important—complete abstinence from alcohol. It was very important to know whether syphilis in the tertiary stage was infective. Sir Jonathan Hutchinson considered it was not, and there was much evidence that tertiary syphilitics did not infect their partners. Since the introduction of the Wassermann test, however, there seemed good reason to doubt that statement, and it now seemed certain that infection could be spread in the tertiary stage. A further question was as to what percentage of latent syphilitics subsequently developed lesions. He was not aware of any figures on this matter. His definite view was that no one with tertiary manifestations ought to marry, both on the grounds of infectivity and of subsequent disability. Even cases of latent syphilis without manifestations risked something by marrying. He would have thought that by now the venereal clinics could have supplied the material to enable this point to be settled.

The physician, said Dr. Panton, was apt to regard the Wassermann reaction wrongly from two or three points of view. He was inclined to regard it as infallible, but everyone was liable to err, and, for safety, the test should be repeated. And mistakes were made in reading or interpreting the result of the test, for it was not a question of it being simply positive or negative, especially in cases in which it was between positive and negative. In a given case of the kind one pathologist would return a feeble negative, another a feeble positive, the reaction being the same. No one would nowadays say a case was cured because of a negative blood, or even spinal fluid negative, for at any time it might revert to positive; moreover, an open, progressive, syphilitic lesion might give a negative Wassermann, both in the blood and the cerebro-spinal fluid. It seemed that certain people did not have a reaction and produce anti-bodies. He asked what was the longest time during which the Wassermann had remained negative and then become positive. The longest time he had seen that was less than two years. A frankly positive Wassermann, he thought, could be confidently taken to mean that active spirochætes still existed somewhere in the body, and no such person could be advised to marry. He did not think the pathologist was the right person to answer the inquirer's question as to marriage, and certainly the dermatologist was not. His practice was to send such inquirers to the general physician for a thorough overhaul.

### *Discussion.*

The PRESIDENT agreed as to the intermittent character of syphilis. To some of the questions which had been propounded he thought there never would be an answer, as so much dependence had to be placed on what was told by the patient. And who could say that it was always the husband to whom a wife owed her infection? He believed it was true in the main that four years after the primary disease it was rare for a man to give the disease to his wife. And yet a case was known in which that occurred 18 years after the chancre. The greatest help in these matters could be given by the general practitioner, for to him the vast majority of cases went in the first place, and he kept in touch with the family happenings. Some patients lost their immunity and became infected again.

Captain F. C. DOBLE considered that too pessimistic an attitude led to a condition which was worse than the disease—namely, syphilophobia, which sometimes eventuated in suicide. Syphilis was worse in a woman than in a man, and every woman who had had syphilis at any time should resume treatment as soon as she became pregnant. He agreed that a very important consideration was whether the syphilitic husband was likely to be an encumbrance to his wife.

Dr. B. B. SHARPE said he was now more pessimistic about the disease than before he heard the two opening addresses. He knew of cases in which syphilis had been transmitted to the second and third generation. It was easier cured in the third generation than in the second. In doubtful cases in which advice was sought, the man should be required to consult the woman, and if she cared to take the risk, no objection should be taken.

Colonel E. G. **FFRENCH** considered the problem was really one of treatment. If a primary case had been adequately treated for years, permission to marry could safely be given, he thought. In a case in which the disease was in the secondary stage before treatment was commenced, there should be an interval of four or five years. If a man had, at consultation, a positive Wassermann, he should not be given permission to marry for seven to ten years.

Colonel L. W. **HARRISON** said there were cases in which the disease had been transmitted many more years than five after the primary chancre, but he had not personally known one. He thought a man might safely marry if he had been well treated, if five years had elapsed, and his cerebro-spinal fluid had remained Wassermann-negative two years. He looked upon a man with a positive Wassermann as a candidate for disabilities later which would probably incapacitate him. He considered that a patient under the influence of treatment was very unlikely to transmit the disease, as the spirochætes would not be allowed to get into the semen. Certainly a woman who had been syphilitic should have treatment at each pregnancy, on account of the great intimacy between mother and child.

Dr. **MARGARET RORKE** quoted two cases in which syphilitic children were born, the parents of whom were said never to have had syphilis, but she found they were tabetics. She agreed as to the need of a guarded prognosis, and also that a woman who had had syphilis, however long ago, should have treatment at every pregnancy.

### *Reply.*

Dr. **RIDDOCH**, in reply, defended his pessimism, and said he thought that, generally, there was too much complacency about the whole matter. He had hopes that many of the questions propounded could be answered, especially as syphilis was nowadays more freely owned to and talked about. At the London Hospital there was a mass of information on the subject awaiting analysis and summarisation which would give valuable data when dealt with.

Dr. **PANTON** also briefly replied. He said the Wassermann was not an evidence of immunity. He had had very little success with provocative doses in the serum reactions.

---

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF OBSTETRICS.

AT a meeting of this Section held on March 12th Dr. D. G. **MADILL**, the President, took the chair, and Dr. **BETHEL SOLOMONS** and Sir **JOHN LUMSDEN** read a short communication on

### *An Unusual Case of Pyrexia.*

The patient, aged 22, had first been seen by Sir John Lumsden suffering from general debility with pyrexia. There had been an influenzal form of attack from which she had recovered. Her symptoms suggested enteric fever, but tests for typhoid and paratyphoid A and B were negative. Sleep was indifferent. For six weeks there was some rise of temperature, the lowest record being 98·8° F. and the highest 102·8°. As no definite cause of the pyrexia could be established, Dr. Solomons examined her recto-abdominally. Finding some fullness in each lateral fornix, he advised vagino-abdominal examination under anæsthesia. The finding then was the same and a diagnosis of tuberculous salpingitis was made.

The blood examination was as follows: Leucocytes, 38,000 per c.mm. Differential count: Polymorphonuclears, 53 per cent.; lymphocytes, 33 per cent.; eosinophils, 7 per cent.; transitional, 7 per cent.

When the abdomen was opened the tubes were found to be slightly thickened and larger than normal, with closed fimbriated ends. Tubercles were not present. It was decided to remove the tubes, which were taken away in their entirety. The ovaries were bound up with them, but it was possible to spare a small portion of the left ovary. After 10 days the pyrexia subsided and the temperature remained normal. The microscopic examination made the diagnosis evident, the submucosa being packed with giant cells.

Two months later the patient again became ill and consulted Dr. F. C. Purser, who diagnosed encephalitis lethargica. She had in addition an attack of diphtheria, to which she ultimately succumbed.

Sir **JOHN LUMSDEN** said that this was an interesting and puzzling case.

When he first saw the patient she gave a history of having been ill for some weeks and of having had an attack about a month previously of what would appear to have been influenza, though her doctor had called it food poisoning. He personally thought that it was an attack of gastric influenza. Her pulse was 100, her tongue was furred, and the apex beat was a little bit out; and he thought that possibly there was a certain amount of myocarditis.

The patient went away, but a few days later returned, and he put her to bed in hospital. Her tongue was still furred; she was febrile, rather constipated, and hard to feed. A blood culture and a Widal test were both negative. There were at that time no symptoms whatsoever of encephalitis lethargica. He suspected, however, that there was some tuberculous focus, although there was absolutely nothing to be made out in the lungs. The epigastrium was tender, and there was nausea if food was pushed at all, which made him think that there was something wrong in the abdomen. Dr. Abrahamson then saw the case with him, and they came to the conclusion that it was a case of tuberculous peritonitis, but asked Dr. Solomons to see her. Dr. Solomons saw her, and operated; after the operation she remained febrile for about 14 days, but then her temperature came down. During convalescence she became rather emotional, but improved enough to be sent to the country. Some time later Dr. Purser saw her, as he (Sir John Lumsden) was away, and Dr. Purser diagnosed encephalitis lethargica. It was, of course, just possible that the girl had had encephalitis lethargica all through, but he did not think it probable. She then developed diphtheria and died.

Dr. L. **CASSIDY** asked how the diagnosis in this case had been arrived at. If tuberculous salpingitis was to be taken as a reason for the state the tubes were found in, it seemed to him rather an extraordinary procedure to mutilate a young unmarried girl on evidence which to him seemed insufficient. Even the microscopical description of the tubes did not seem to him sufficient to account for the clinical symptoms in the case as described by Dr. Solomons and Sir John Lumsden. He, personally, would have thought that the condition was due either to tuberculous meningitis or encephalitis lethargica. He felt that in cases of this kind the wisdom of applying either radium or X rays should always be considered. During the last few years he had seen about 30 such cases and with two exceptions had always found that good results followed treatment by radium or X rays. The symptoms in this case, he thought, largely pointed to a condition of tuberculosis, possibly in the upper abdomen, but not to a condition which would justify removal of the tubes.

Dr. L. **ABRAHAMSON** said that certainly when he saw her there was no sign of either meningitis or encephalitis, and he did not think that when Dr. Purser saw her she had meningitis, as the cerebro-spinal fluid was not under tension, and he had never seen a case of tuberculous meningitis in which the cerebro-spinal fluid was not under tension. Encephalitis lethargica was sometimes hard to diagnose, but when this patient was seen by Dr. Purser the symptoms were apparently so typical that the diagnosis was obvious. When he (Dr. Abrahamson) saw her she was suffering from pyrexia and her symptoms were all due to this. The only symptom that she had, however, was vague abdominal pain. No evidence of tuberculosis could be found either in the chest or in the abdomen. When the contents of the tubes were cultured for tubercle bacilli the result was negative, but tubercle bacilli were found in sections. No naked eye tubercles could be seen, but microscopically they were easily seen. He thought that removal of the tubes in this case was absolutely justified, and that the result was satisfactory, and he believed that but for the development of encephalitis lethargica the patient would have lived. She died from an intercurrent disease which had nothing to do with the original complaint. The result of X ray treatment in these cases was that there was no internal secretion of the ovaries, whereas in this case, after operation, a little ovary had been left.

Dr. Gibbon FitzGibbon said that the question whether active tuberculous tubes should be removed was a much discussed one; he, personally, always took them away in cases in which there was evidence of advancing active disease. If the tubes were not removed the patient was left with a disease. Removal could not leave the patient more sterile than she was before, because tuberculous tubes were functionally useless.

Prof. R. J. Rowlette drew attention to the high blood count in this case, which at the time the count was taken was apparently one of tuberculosis. He thought that this was possible evidence of an extreme degree of purely tuberculous toxæmia. Nowadays pyrexia was regarded as a symptom not of tuberculous toxæmia, but of septic toxæmia; but in this case it was proved to be a symptom of tuberculous toxæmia. A curious feature of the case was that diphtheria occurred when encephalitis lethargica was also present. He thought it possible that tuberculin might have done the girl good, but it had been necessary to open the abdomen to see what disease was present, and when the tubes were found to be tuberculous there would have been considerable risk in leaving them alone. He therefore approved of Dr. Solomons's treatment.

Dr. J. S. Quin asked if erosion of the cervix was present or if there was any leucorrhœa.

Dr. G. W. Theobald referred to a patient who had been admitted to hospital said to be suffering from eclampsia. A lumbar puncture was done, but the patient died five minutes afterwards. At autopsy every gland was found to be a mass of tuberculosis. In the case described by Dr. Solomons, assuming that the patient had tuberculosis, encephalitis lethargica, and diphtheria, was it right to assume that the tuberculosis of the tubes was sufficient to cause the very definite symptoms from which she had suffered for a long period of time? Was it not likely that there was some focus of tuberculous infection elsewhere in the body?

Dr. Solomons, in reply to Dr. Cassidy, said that the diagnosis was arrived at (1) by excluding other diseases, (2) by bimanual examination, and (3) by the appearance of the tubes taken in conjunction with the history of the case. He disagreed entirely with Dr. Cassidy about the treatment. He had a very large experience of tuberculosis of the tubes; he had tried palliative salpingostomy in cases of sterility in these cases, and had found that the results were bad. Either there was no cure of the sterility or there was recurrence of the disease. He therefore recommended strongly complete salpingectomy for tuberculosis of the tubes; in this way the disease was removed. The chance of pregnancy before removal was nil. There was no need to extirpate the uterus, for if it was infected the infection cleared up after salpingectomy. Treatment by radium and X rays was useful in general abdominal tuberculosis. In this case there was no erosion of the cervix, nor was there leucorrhœa. So far as could be felt there was no tuberculous disease higher up in the abdomen. He was convinced that this was a case of tuberculosis of the tubes causing pyrexia and cured by operation.

Dr. Theobald read a paper on the Contraction Ring in Labour.

## JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, ST. ANDREWS.

On March 23rd Dr. J. H. P. Paton delivered a lecture on

### *Youthful Irregularity of the Pulse.*

Mackenzie, he said, had pointed out that an irregular pulse was a physiological phenomenon of youth, which was exaggerated in convalescence from febrile illness. It tended to disappear in some febrile complaints, and its return was evidence that the toxic process causing its disappearance had become quiescent. The pulse was regular in only four out of 500 consecutive girls whom Dr. Paton had examined on admission to school. Each of the four in whom it was absent had proved to be suffering from a febrile complaint. From these facts, and from a large number of observations spread over some years, he concluded that the irregularity was never absent, except in disease, in girls from 8 to 16 years of age. Its absence was a valuable sign of ill-health, and its return in a marked form in convalescence had the same significance as the fall of temperature, and indicated that active toxæmia had ceased. This fact was evidently not generally known, since it was common for young persons to have their activities restricted because the pulse was irregular. The terms arrhythmia and irregularity carried a significance of abnormality which was doubtless the reason why Mackenzie's view had not received wider recognition. It was absence of irregularity that was the symptom of disease.

On March 30th Dr. Paton gave a second lecture in which he discussed the mechanism responsible for the irregularity of the youthful heart-beat. However simple an explanation of the phenomena might seem to some people, it was obvious from the views expressed by Mackenzie in the fourth edition of his "Diseases of the Heart" that none of them satisfied him completely. Mackenzie believed that both sympathetic and vagus impulses played a part in producing the arrhythmia, and concluded that the source of the impulses was probably to be found in the activity of the respiratory muscles or in some other peripheral source. He believed that the disappearance of the irregularity in febrile conditions was due to the action of toxins of microbic origin on the sino-auricular node, resulting in such an increase of rate that the irregularity was abolished. Referring to impulses from within the heart itself and to the variations in carbonic-acid content of the blood during respiration as possible causes of sinus arrhythmia, Dr. Paton said that the clinical evidence which he had been able to collect indicated that the irregularity had its origin in the activity of extracardiac reflex arcs of which the cardiac fibres of the vagus and sympathetic caused the effector response. The problem then could be stated simply: Where in health did the impulses determining the activity of these nerves originate and at what points were the reflex arcs interfered with in disease? Admittedly, no certain conclusions could be reached, but there was evidence which suggested that the impulses hastening the rate in inspiration were probably circulatory in origin, and had their source in the variation of the pulmonary capillaries in response to variation in intrathoracic pressure. The vagal stimuli inducing slowing in expiration probably originated in the variations of pressure or circulation in the abdomen. No pulmonary condition was known which induced slowing of the heart. He looked on the variation in rate as an attempt at adjustment to the changes in distribution of blood as between the pulmonary and systemic circulations, resulting from alterations in the capacity of the chest. The difficulty of the subject was due to the opposing action of the two cardiac nerves; it was impossible to differentiate the effect due to each.

A post-graduate course of 50 lectures and demonstrations for general practitioners is to be held at the Institute, St. Andrews, from June 14th to 30th. The subjects to be dealt with cover a large field, and those who wish to carry out practical work in the laboratories will be given facilities. The fee for the course is five guineas.

---

*Corrigendum.*—Dr. G. Roche Lynch informs us that he did not make the remarks attributed to him in our report of the discussion on Lead in Malignant Disease at the Medical Society of London (THE LANCET, March 27th, p. 659).

# Reviews and Notices of Books.

## THE PRODUCTION OF LOCAL IMMUNITY.

*Immunisation Locale Pansements Spécifiques.* By A. BESREDKA. Paris: Masson and Cie. 1925. Pp. 252. Fr.20.

THE title of this book is a little ambitious. Its scope is really limited to the phenomena exhibited when certain strains of infective bacteria are applied to the skin by the author's special method of "pansements spécifiques," and when certain of the intestinal groups of bacteria are administered by mouth. The author has here brought together the materials of experimental work, brief records of which have appeared from time to time since the war in the *Annales de l'Institut Pasteur.* The work has been further elaborated with historical reviews of the subject and a discussion of the mechanism of this particular type of immunity and theories—which latter the author points out are still very much in the evolutionary stage. Briefly stated, Prof. Besredka's method consists in infecting the shaved skin of the animal by the application of a dressing soaked in an attenuated or killed culture of the organism. This application is followed by local reaction of the surrounding skin, which lasts from four to six days and then subsides. The cuti-vaccination thus effected affords protection for the animal against a subsequent infecting dose of the same organism large enough to kill a control animal. Similar effects may be produced by intradermal injection. In both cases the animal acquires immunity, but the serum does not possess the power of protecting a normal animal against infection. This work has been carried out chiefly with *B. anthracis*, staphylococci, and streptococci. Similar experiments have been made by the intestinal route in the case of the dysentery group of organisms, the intestinal mucosa in this case appearing to act in the same way as does the intact skin in the case of anthrax bacilli, streptococci, and staphylococci. Finally, in the typhoid group, Prof. Besredka has been able to produce similar results by means of sensitising the intestinal mucosa by a preliminary treatment with ox bile. The book contains numerous data with regard to prophylactic inoculation against anthrax carried out on larger animals under agricultural conditions and against dysentery and typhoid fever on soldiers and refugees. The work contains many suggestive ideas and comes at an opportune time when the intradermal route for tuberculin testing and for other skin tests is becoming more and more used in applied clinical immunity. A good bibliography would have added considerably to its value.

## BIRTH CONTROL AND THE STATE.

A Plea and a Forecast. By C. P. BLACKER, *M.C.*, M.R.C.S., L.R.C.P. London: Kegan, Paul, Trench, Trübner and Co., Ltd.; New York: E. P. Dutton and Co. 1926. Pp. 95. 2*s.* 6*d.*

THIS is a temperate and scholarly survey of the arguments for and against the encouragement of the practice of birth control. Dr. Blacker gives the impression that the controversy has aroused in him keen interest but no morbid excitement; he thus restores to a wholesome commonplace level a subject which some have exalted to an ecstatic plane, while others have trampled on it with dirty feet. Military, economic, religious, and socio-political arguments against contraception are here stated in trenchant terms; the arguments in favour of its wider practice are, if anything, less forcibly set out, so little has the author's own bias been allowed to prejudice the reader. For example, the prevalence of attempted abortion in the class where birth control is least practised is certainly not over-emphasised, and the estimate, founded on inquiries, that more than half the infants born in a hospital district are unwanted is not, we think, too high. The conclusion drawn from consideration of the complex problems involved is that if the existing form of civilisation is to have any permanence, the necessity for controlling population will have to be realised and striven for by the educated.

The main purpose of the book is to ask for an expression of an opinion by the medical profession as a whole, or in large majority, designed to induce the Minister of Health to permit medical officers of welfare centres to give instruction in birth control at their discretion. The admission, disconcertingly sandwiched in the middle of the book, that no really satisfactory contraceptive as yet exists, renders this plea less effective. Coitus interruptus is justly condemned as harmful to both sexes; the penile sheath is not likely to be used by the type of individual whose procreation it is desirable to restrict. There remain chemical suppositories or some form of rubber cap for use by the woman. Until a method is found which involves less manipulation of the female genital organs, less risk of occluding discharges from the cervix, and gives greater security than any of the chemical preparations now in use, it will be difficult to convince medical men that the time is ripe for official propaganda. It is fair to state that, provided information may be disseminated from welfare centres to suitable cases, Dr. Blacker is in favour of a veto on certain unofficial methods of propaganda, such as newspaper advertisements.

It is regrettable that in an essay built on such broad historical and biological foundations a critical inquiry as to the origin of the most recent world war should have been included. Concrete examples are admittedly more persuasive than abstract ones, but the subject of contraception is already so controversial that it is best supported where possible by examples from the history of times other than our own.

## SURGERY.

*Die Chirurgie.* Edited by Prof. Dr. M. KIRSCHNER and Prof. Dr. O. NORDMANN. Berlin: Urban and Schwarzenberg. 1925. Vol. V., pp. 521, M.27; Vol. VI., pp. 358, M.21.

TWO further sections in the new system of surgery edited by Kirschner and Nordmann have reached us. Vol. V. deals with the surgery of the kidney, ureter, urethra, penis, testicle, and cord. In itself it forms a text-book of genito-urinary surgery, except for the omission of diseases of the prostate and bladder. Its outlook is continental, and for that reason is of value to English surgeons. The information given appears to be reliable and to follow the usual urological practice. Where there are debatable points the writer gives the facts without inclining to one or other view. For instance, on the question of radical extirpation of the lumbar glands in the treatment of malignant tumours of the testicle, Dr. E. Wehner, the author of this section, asserts that sufficient knowledge has not yet been accumulated to give a judgment as to the advisability of this course being taken. He is also conservative in his attitude towards excision of, or operations upon, the seminal vesicles in tuberculous disease of the urinary tract. The surgery of the kidney and ureter is written by Prof. P. Frangenheim with the assistance of Dr. Wehner, and is a very satisfactory section.

Vol. VI. contains descriptions of the surgery of the mouth, pharynx, and salivary glands by Prof. F. Brüning, and the surgery of the larynx and trachea by Prof. J. Soerensen. The section on the mouth and tongue runs on familiar lines and makes a good treatise on stomatology. In the account of the treatment of cancer of the tongue it is stated that the glands are removed first and the primary growth second. No consideration is given to the reversal of this process. A warning is issued against a too wide application of tonsillectomy, on the grounds that the tonsil has a function, and that to destroy this is undesirable unless there is sufficient cause for doing so.

The chapters dealing with the surgery of the larynx are among the best we have seen in this system of surgery. The account is complete and Prof. Soerensen speaks with the authority of a very large experience. He and Gluck together have performed 788 total extirpations of the larynx. The very high primary mortality has been reduced enormously, so that in one year only 2 out of 100 patients died as the result of the operation. In 120 patients it was necessary to remove the upper part of the œsophagus as well as the larynx, a procedure which increases the mortality to a very great extent, so that of these patients 24 died. The end-results when this large operation is performed are also bad, as only nine were permanently cured. This is the operation the authors recommend for disease of the sinus pyriformis. They regard removal of the growth by lateral pharyngotomy as advocated by W. Trotter in this country as quite inadequate. Laryngectomy has also been performed by them for tuberculous disease of the larynx, but the results do not seem to us to justify its general adoption as a method of treatment.

Both these volumes are illustrated by a large number of coloured as well as black-and-white prints. The high standard set by the former parts of this work has been well maintained.

### EVOLUTION.

*A Naturalist in East Africa.* By G. D. HALE CARPENTER. Oxford: Clarendon Press. 1926. With 25 illustrations, 8 plates of insects, and 3 maps. Pp. 182. 15*s.*

*Evolution.* By J. GRAHAM KERR. London: Macmillan and Co. 1926. With 2 coloured plates and 52 text figures. Pp. 278. 12*s.*

A BUTTERFLY-NET and a copy of Poulton's "Colours of Animals"—though we suspect that he carried this in his heart without burdening his pockets—gave Dr. Carpenter many happy hours while he was wandering about in Uganda and East Africa during the war, generally with no great burden of professional work. And his jolly book hands on a whiff of his gaiety to his readers; anyone with a feeling for natural history in the field will enjoy it and sympathise with the author's zest and excitement in a country which seems to be brimming over with life. And scattered all through are a diversity of observations of interest and many of importance. Dr. Carpenter interprets what he sees in terms of natural selection, and it is certainly impressive to read how he has sat down by a puddle and watched wagtails deliberately pick out one or two kinds from the varied assortment of butterflies which had gathered there to drink. The last chapter gives a full and well-illustrated account of a long series of experiments which he made on the likes and dislikes of a couple of tame monkeys for different insects. Altogether he has provided an excellent sequel to his "Naturalist on Lake Victoria."

Prof. Kerr tells the same tale in a different way. He has written a plain statement of what he believes about evolution and why he believes it. He learned his lessons, he says, in the open and in the tropics, and he has complemented this experience—which Darwin, Huxley, Bates, Wallace, Carpenter, and many others have found to be the unique experience of their lives—by a long and fruitful academic discipline in the laboratory. *Nullius in verba magistri* is a good motto, but the considered opinion of some people is bound to be received with more attention than that of some others; and we believe that this record of the matured results of such a wealth of observation and reflection will find a welcome in a world which has shown signs of being rather restless, and perhaps a little frivolous, about the "Origin of Species." The first five chapters deal with the facts of history, structure, and distribution which lead to the conclusion that evolution has really happened; the next four with heredity and its experimental study; the next with natural selection as the direct cause of evolutionary change; and the remaining five with adaptation, sexual selection, the evolution of communities, and man. In the main, Prof. Kerr adheres to the classical position: evolution is a fact; variability is inherent in all live things; the potency of natural selection is enormous, and the importance which Darwin attached to it has only been increased by the more recent knowledge of Mendelian inheritance, adaptation, and the coördination of the different parts of the body.

### COMPARATIVE PHYSIOLOGY.

By L. T. HOGBEN. London: Sidgwick and Jackson. 1926. With 44 text figures. Pp. 219. 7*s.* 6*d.*

APART from his own researches, Dr. Hogben has already made a useful contribution to the admirable movement for a wider physiological outlook which is represented by the Society for Experimental Biology and its journal by his Introduction to Comparative Physiology written in conjunction with Dr. F. R. Winton. The present book is the first of a series of text-books of animal biology edited by Prof. Julian Huxley, which will be popular if the succeeding volumes maintain the high standard and low price. It surveys in order the general physiology of muscular movement, ciliary action, respiration, nutrition, circulation, endocrines, nervous system, fertilisation, inheritance, and development. It is necessarily brief, but the author has a happy knack of compressing a great deal of information into a very readable narrative. Most physiologists and most zoologists—for it is meant for both parties—will learn something from it, and will probably feel that its chief defect is that there is not more of it. With special comparative physiology it does not pretend to deal; indeed, it will be a long time yet before each animal or group of animals will have a physiology of its own. Dr. Hogben's book will encourage the curious to set about the task of creating one. The page-headings want reconsideration; their utility and importance are often underestimated by book makers.

### PRACTICAL CLINICAL PSYCHIATRY.

For Students and Practitioners. By EDWARD A. STRECKER, A.M., M.D., Professor of Nervous and Mental Diseases, Jefferson Medical College, Philadelphia; and FRANKLIN G. EBAUGH, A.B., M.D., Professor of Psychiatry, University of Colorado. Philadelphia: P. Blakiston's Son and Co. 1925. Pp. 375.

PSYCHIATRY stands out as a most elusive and difficult branch of medical science, possessing little undisputed pathology or ætiology; very little is known of the causation of the majority of mental disorders, and their clinical pictures differ so widely that it is almost true that every patient has his own type of psychosis. Small wonder that of the many text-books on the subject, often admirable in other ways, hardly any is of much use to the student save as an academic introduction to the subject. These American authors have realised that a little practical experience is worth more than much study, and have taken the bold line of refusing to attempt any but the briefest theoretical annotation and general description. In default of *actually* conducting the student round the wards they come as near to it as possible, and instead of discussing the possible variations of every known form of disorder they select a number of the commonest complaints and describe an actual case of each one, chosen to present a clinical picture which shall be typical of the majority of cases of the same type, with full history and the detailed results of examination. It is obvious that they have only covered a small part of what its exponents understand by psychiatr but they have made that part both interesting and concrete. The book is not to be recommended as the sole text-book for candidates for examination, but the student will probably learn far more from these specimen cases than he would from any of the larger standard works. He will, moreover, gain a grasp of the outstanding features of the commoner types of mental disease that will enable him to connect his theoretical knowledge with the cases he meets in the wards or out-patients' department. For the rest, the classification is not admirable, as it seems to have little system underlying it and to be impossible to memorise; the English is turgid and the diagrams are obscure. The scheme of examination, however, placed early in the book, is thorough and practical; the bibliography is very complete, and there are several good photographs. The volume deserves to become popular not only with students but with general practitioners, social workers, and others whose occupation demands a practical rather than an exhaustive theoretical knowledge of this difficult subject.

## POPULATION.

By A. M. CARR-SAUNDERS. In the "World's Manuals" Series. London: Oxford University Press. 1925. Pp. 112. 2s. 6d.

*The Natural Increase of Mankind.* By J. SHIRLEY SWEENEY, D.Sc. With an introduction by WILLIAM H. WELCH, M.D. Baltimore: The Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1926. Pp. 185. $4.00.

*The Biology of Population Growth.* By RAYMOND PEARL, Director of the Institute of Biological Research, Johns Hopkins University. New York: Alfred A. Knopf. 1925. Pp. 260. $3.50.

ONE of the most insistent of post-war problems is that of population. Is Great Britain over-populated? Can birth control cure unemployment? Is population-pressure an important cause of war? These are some of the questions arising directly from the excogitation of recent and present political affairs. Expert witnesses are found in opposition, and feeling tends to run high when reformers disagree on matters of fundamental importance to the welfare of mankind. It is of all the more happy augury that men who have a scientific rather than humanitarian interest should be publishing at present the results of their careful research into the causes of population, growth, and the natural laws which govern the increase of the human race.

The popular handbook by Mr. Carr-Saunders, while no substitute for the valuable study which he published four years ago,[1] is an admirable introduction to the subject, and contains much useful statistical information. The diagram comparing the rates of growth of various European countries and of the United States is clear and interesting, although a fairer comparison of such rates would be obtained by plotting the millions of inhabitants upon logarithmic rather than on arithmetic scale.

Dr. Sweeney describes his book, prepared as a thesis for the D.Sc. in Public Health of Johns Hopkins University, as an Analysis of Population as a World Problem. It is "the most comprehensive world-wide study of this subject made in recent years by the application of a uniform statistical method." Dr. Welch says so, and his authority is not to be gainsaid. Indeed, the apparent care with which the author marshals authority, pro and con, on every issue that he raises, almost serves at times to obliterate his own personality. Yet he has his philosophy, and it emerges eventually in a scheme for an international agreement to control numbers by a league of stationary populations. He believes, as Mr. Carr-Saunders does, that our populations are growing too large, though his dislike of dense population is based on somewhat different considerations. Mr. Carr-Saunders sees a menace to the quality of life from over-urbanisation. His viewpoint here, as in other questions, is original and stimulating. Dr. Sweeney's chief anxiety seems to be the inevitability of international conflict if "relative over-population" is allowed to proceed—as, in the author's opinion, it almost certainly will. His suggestion is to make birth control not merely permissible, but even compulsory according to a scale fixed by concord between the competing powers.

The solution seems plausible enough in the context, but faith in its efficacy is rudely shaken by a perusal of Dr. Pearl's latest contribution to the biology of population growth. Herein, the inevitable laws formerly expounded in "Studies in Human Biology" are by further researches made to appear still more inexorable. A particularly striking example is the growth of the native population of Algeria. In that country no widely spread public health control can have affected death-rates, no artificial interference with conception can have slackened the birth-rate, yet the population climbs just as surely the mathematical slope of the logistic curve as in more civilised countries where water is never drunk without its due supply of chlorine, and where contraception, whether legal or illegal, has its innumerable devotees. Since Dr. Pearl read his paper to the Baltimore Conference on Birth Control in 1923[2] he has changed his mind somewhat on the menace of population growth. He no longer believes that a refusal to control the rate of reproduction will have the effect that "our children's grandchildren and great-grandchildren will probably see such an amount of suffering, a standard of living so lowered, as to make these parlous times seem paradise indeed." On the contrary, he takes comfort now from the thought that France "is a country with a population near the maximum for the present cycle. But he who thinks France an unhappy or wretched country is both ignorant and stupid." But France reaches her asymptote with a population less dense than that of England and Wales, though our country is still on the climb! Our slope is a steeper slope, and Dr. Pearl is keen to point out the great rewards coming to that biometrician who will determine for us the natural laws which dictate what slope the logistic curve of growth shall take for any particular people.

## GILLES DE RAIS: THE ORIGINAL BLUEBEARD.

By A. L. VINCENT and CLARE BINNS. Introduction by M. HAMBLIN SMITH, M.A., M.D., Medical Officer H.M. Prison, Birmingham. London: A. M. Philpot, Ltd. 1926. Pp. 221. 8s. 6d.

Gilles de Rais is one of the most outstanding examples in history of the sexual pervert, and although everyone has heard of him under the name of Gilles de Retz as the origin of the Bluebeard legend, he had but one wife, and his crimes were perpetrated, chiefly at any rate, against young men and lads. It appears that this is the first account in English of his horrible life, and the story is full though quite discreetly told. It shows the descent of a highly-born and enormously wealthy youth through profligacy to necromancy, and through foulness of all sorts to multiple murder. The degraded man at several stages in his career gave proofs of capacity for better things. More than once he proved himself a brave and capable soldier, was a valuable comrade in arms of Joan of Arc, and became a Marshal of France. He was also a great stage manager and the author of the libretto in some of the numerous pageants which he instituted. When at last his enormities brought their reward he met execution with fortitude, not attempting any apology for his crimes, and apparently believing that repentance in this world would stand him in the necessary stead elsewhere. A copious bibliography shows how many authors of medical and scientific repute have employed the Lord of Champtocé as an illustration of perversion.

to the health of the employees, but improved housing should come concurrently.

The Commissioners recognise in frank terms that the industry presents for investigation and observation facts and factors so far hardly realised. More than 1,000,000 men and lads are employed under working conditions which, while broadly alike, differ in minor details on the separate coalfields. The mortality experienced by coal miners is fairly low; yet the Lancashire miner, with the South Wales miner not far behind, has a mortality nearly double that of his fellow in the Nottingham area. Now the Lancashire and South Wales miners have always manifested the greatest unrest as a class; unrest in the industry appears therefore quite clearly as a psychological expression of ill-being. The time at the disposal of the Commissioners was too short for them to await the result of investigations into such matters—to be conclusive, a research of years rather than of months would have been necessary—but the relation of unrest to mortality must be borne in mind as a practical as well as a humanitarian argument for reforms. Apart from accidents and industrial diseases there is no evidence to show that mining is not a healthy occupation. But the mining industry holds an unenviable priority with regard to the incidents and accidents for which compensation is made, as well as for occupational diseases, and the work already undertaken by the Medical Research Council should be recalled in connexion with the Report. An expert committee of the Council has already issued reports on many diseases incidental to miners, and is continuing its researches into miners' nystagmus, which accounts for more cases, and a larger sum paid out every year, than all other compensation diseases taken together. The conclusions here do not clash with those arrived at by Mr. POOLEY in an article which we publish this week, and all observers seem agreed to consider the pathology of the disease still not clear, and its occurrence not of the sinister importance that might seem postulated by the money paid in compensation. Beat-knee, -hand, and elbow, which stand respectively second, third and ual fourth with lead poisoning in the list of occupa-
nal diseases, have also been considered by the
dical Research Council's committee, and an inquiry
o the relation of lost time to sickness at different
llieries is under weigh. Another research is dis-
ing the existence, previously only dimly suspected,
silicosis among a small group of underground men
use pneumatic drills on hard rock; while the
iological conditions of underground ventilation
also being closely studied. Meanwhile the Safety
Mines Research Board, financed from the Welfare
d, is covering a wide and comprehensive field of
rch aimed at preventing explosions and render-
mining work less dangerous. The activities
urated by the Fund are praised by the Com-
ners; already their influence can be traced in
relations existing between employers and

sure that the connexion between mortality
has always been of profound importance
stry. The successful dealing with the
s of industrial disease, and the estab-
ithead baths throughout the coalfields,
o improve the physical and mental
he miners, of whom to-day only some
1,000,000, going below ground daily,
of a bath at the pithead, but from
nt of view the housing question is
ne. To set the foundations of the
onomically will tax the ingenuity

of all concerned as well as their willingness to make sacrifices, but no economical reform which fails to take the health of the miner into consideration has the slightest chance of life, and but little chance of being born alive. How far the various pathological conditions are due to or are promoted by bad housing, and what relation there may be between bad environment and the occurrence of accidents, can only be subjects of rough estimate. The numerous points could not well be summarised to make a reference for a body of expert inquirers, but apart from the quite possibly mischievous influence of bad housing upon the mining industry, in particular all medical men will feel that the housing conditions of the miners must be remedied. These conditions are often very bad. The Report sets out what is indeed common knowledge. Many of the old mining villages consist of poorly constructed cottages, small and frequently overcrowded, with sanitary arrangements that are primitive and inadequate. This, though shocking, is readily to be understood when we remember that the mining village was often built to serve a temporary purpose; and it is right to say here that some of the new colliery companies have planned for the miners well-constructed and well-equipped garden villages, while in districts where the housing is usually poor there may be found groups of excellent new cottages built by enterprising proprietors or local authorities. In certain collieries the influence of the free colliery house is baleful; the great majority of these houses are atrocious, and they have set a low standard for the whole of the housing in Northumberland and Durham. There is thus every gradation between good and bad housing, but the merits of the good do not cancel the evils of the bad. The necessity for a levelling-up of the housing conditions of miners is paramount, and we trust that it will be kept steadily in the minds of those who have now to deal with the anxious and complicated situation.

## THE RISKS OF HYPOTHESIS.

In his Goulstonian Lectures, which are appearing in our columns, Dr. Bernard Hart opens up a wide subject when he lays down principles by which the claims of scientific hypotheses, especially concerning psychopathology, can be tested and appraised. Mankind has an innate desire to know, and in satisfaction of this desire the most primitive races produce speculations belonging to the conceptual as opposed to the perceptual level. There is every gradation between the simple speculation of the savage and the complex hypothesis of the man of science; each is arrived at by the pressure of the same psychological motive, each would appeal to the tribunal of experience, and in the case of each there is felt a sense of power when a new generalisation is made. Danger lies in this sense of power, for its gratification may lead to a specious appearance of knowledge when knowledge has not yet been attained; the man who believed thunder to be the voice of an offended deity probably felt immensely superior to the ignoramus who lacked that explanation.

Dr. Hart, perhaps, had in mind such a danger when he warned us that the desired consummation of reducing the concepts of psychology to the wider concepts of physiology is brought no nearer by pretending that it has been attained. He gives the three successive steps, as enunciated by Karl Pearson, which distinguish the scientific method, and makes the claim that it is the method, not the material handled, which characterises science. These steps are the collection of facts, their classification, and finally the construction of conceptions which serve to explain them. Scientific canons, ensuring that each step is kept in close contact with observation, are needed to check the primitive tendency to believe that any hypothesis is better than a confession of ignorance, for at each step there may be only a semblance of scientific method; the facts may be wrongly observed, their collection may be inadequate, and the generalisations may be premature. Perhaps the commonest error has been to leap to a final conception before the observation and collection of facts are sufficient, and this error plainly arises from the strong desire to believe that we know. When we act upon such a premature hypothesis, our results are probably futile and the greatest evil may lie in the arrest of inquiry. A notable result of the hurried leap to a conclusion is found in the case of hysteria. Attributed, on observations not entirely baseless, to the wanderings of the unsatisfied uterus, hysteria came to be treated with evil-tasting drugs intended to drive that organ back to its proper place, and, although this therapeutic aim has been lost, the use of the drugs has survived. A fuller collection of the facts upon which the theory was thus inadequately based might have led our professional forbears to anticipate some of the findings of modern psychopathology, but it is likely that even in the days of Galen there was a tendency to seek in physiological terms for a satisfying explanation of psychological phenomena. Such survivals as lunacy, melancholia, and hypochondria indicate the range of this tendency, and the use of concepts like nerve exhaustion and brain fag still satisfies the desire to believe we know the unknown.

Yet, as Dr. Hart points out, we are not prevented from using a working hypothesis which is independent of phenomenal reality. Although its existence is not a fact of experience yet the scientific conception of the ether is most fruitful; and the theory of the indivisible atom produced discoveries which led to its own downfall, thus demonstrating, by a curious paradox, at the same time both its value and its invalidity. Psychology, like other sciences, has produced numerous hypotheses. Faculty psychology has proved barren; intellectualist psychology has proved erroneous; instinct psychology provides little more than a collection of algebraic expressions useful for resuming facts under convenient headings; suggestionist psychology, as Dr. Hart shows, has proved disastrously soothing. It seems that the hypothesis of the unconscious has now become fruitful after a long period of relative futility. Framed to account for curious phenomena which fell outside the bounds of ordinary rational experience, it received no further definition for many years until Freud found it indispensable to explain a large number of newly observed facts. It is certainly free from the appeal to a desire for easy explanations, and, though this places it at a disadvantage when confronted by more facile hypotheses expressed in terms of the concrete, yet this freedom should encourage us not to evade its difficulties in favour of more alluring, because more facile, speculations.

## THE CARDIAC CLINIC.

We referred recently to the work of the American Association for the Prevention and Relief of Heart Disease and to their official publication, the *American Heart Journal*. In the *New York State Journal of Medicine* for Nov. 1st, 1925, Dr. John Wyckoff discusses the scope and organisation of clinics for the treatment of cardiac cases. He points out that any special clinic must necessarily overlap fields of medicine other than that to which it is particularly devoted, and consequently it is essential for the cardiac clinic to be in close touch with other departments, such as the venereal clinic, the oto-laryngological clinic, and the dental clinic. In addition, there should be available the laboratory facilities of a large general hospital, both for pathological investigations and for special studies, such as X ray and electro-cardiographic examinations. Dr WYCKOFF emphasises the importance of close association of the clinic with an in-patient department, not only in the interests of the patients, but also on account of its instructive value in enabling the young physician to study the different aspects of heart disease. As he aptly puts it, "in the ward one sees but a small cross-section of the cardiac's life, whereas in the ambulatory clinic one learns the course of chronic heart disease, its management and treatment." Very few, if any, physicians can hope to keep in close touch with the recent advances in all fields of medicine, and if patients are to get the benefit of these advances, specialisation is a necessity On the other hand, the specialist must work in the closest coöperation with those of his colleagues whose interests lie in other fields.

The functions of the cardiac clinic are to keep the ambulatory patient with organic heart disease in the best possible health for as long a time as possible; this involves first a full and accurate diagnosis and, secondly, treatment. The diagnosis comprises not merely the structural and functional considerations, but also a careful survey of the social conditions, environment, and habits, as well as the financial status and responsibilities of the patient Unless these latter points receive due consideration, the actual medical treatment cannot yield the best results. For this purpose the staff of the clinic have to rely principally on the social service branch, whose members visit the patients in their homes and are in a position to furnish the necessary information on these points to the medical officer. In order that the social service workers may not waste their time in attempting to cover too wide an area, any one clinic should confine its attentions to such patients as live within easy range of the hospital, and when a patient moves his residence he should be transferred to another clinic. The staff of the clinic includes a clerical section composed of lay workers, whose duty it is to relieve the medical staff of all non technical matters, and to facilitate the following up of cases and statistical research by an efficient system of record-keeping and cross-indexing As cases come up for re-examination it should be possible to obtain the latest data concerning their progress and the results of previous treatment, in order that these may be carefully reviewed before the future line of treatment is decided upon A regular routine in the examination of patients is essential where large numbers of patients are being dealt with, and the method which has been adopted at the Belle Vue Hospital is as follows. At the first visit the patient's history is taken, he is examined, and temporary treatment is instituted The social service worker then visits his home. The following week special examinations of the nose and throat, electrocardiogram and X ray are made, while on his third visit he is seen by the dentist, and the physician in charge has at his disposal the full information necessary to enable him to institute a permanent line of treatment.

Dr WYCKOFF raises an important point with regard to the transference of patients from the children's to the adult clinic. It is at this stage that patients are most liable to be lost sight of, and he suggests that the best remedy is to form an intermediate adolescent clinic which will take them over at the age of 16 and subsequently transfer them to the adult clinic at the age of 18, when they are more likely to realise the importance of continuing their attendance. The writer points out the importance of differentiating between cases which are likely to benefit from a period in a convalescent home from those which cannot have any reasonable hope of building up their cardiac reserve by convalescent treatment. For although these latter may be able to live within their cardiac reserve for several months while at the convalescent home, sooner or later they are bound to become bed cases. They occupy accommodation at the convalescent home without the prospect of deriving any corresponding benefit therefrom, and provision should be made for them in the form of a hospital for permanently disabled

The work which is being done by the cardiac clinics in America is of economic value. It enables those who are the subjects of heart disease, but still able to work, to obtain expert advice and treatment, and so diminishes the wastage from this cause during the most productive period of life

---

## THE JOINT TUBERCULOSIS COUNCIL.

IN the general development of tuberculosis work which followed the provision of sanatorium benefit and the appointment of tuberculosis officers a need was apparent for close coöperation between the many and varied bodies and individuals concerned. But such coöperation, with resulting coördination of effort, was not by any means easily attainable. Although consultants, tuberculosis officers, research workers, medical superintendents of sanatoriums, and others all had their own circles of interest and information, those circles and their societies had few opportunities for effective joint discussion of common problems or for common action. In order to meet this state of affairs the Joint Tuberculosis Council was set up, and has gone far to remedy the defects of organisation. The Council comprises representatives of practically all societies, associations, and Government departments actively concerned in tuberculosis work. It meets quarterly, or more often as may be required, and the considerable amount of work it has done since its inception in March, 1924, shows that the meetings are not merely formal A special committee has taken in hand projects for collective research, keeping in touch with the Medical Research Council Post-graduate courses have been held (some of which are announced on page 790), and are being further developed Evidence has been given before the Royal Commission on National Health Insurance; and such subjects as the employment of tuberculous persons have been considered in practical detail The whole object of, and justification for, the Council is the attainment of coöperation and coördination amongst all tuberculosis workers With such an object and such practical evidence of useful work already performed the Council is to be welcomed as a valuable addition to the antituberculosis forces of the country. Sir HENRY GAUVAIN is the chairman, and Dr E. WARD the hon secretary

---

AN election to the Council of the Royal College of Surgeons of England will be held on Thursday, July 1st, 1926 There are four vacancies, and the following 12 have signified their intention to be candidates: Mr E. W. Hey Groves, Sir Herbert Waterhouse, Mr. Warren Low, Mr. W. E Miles, Mr. H J. Paterson, Mr Victor Bonney, Mr. J. P. Lockhart-Mummery, Mr Philip Turner, Mr C. A. R Nitch, Mr. Hugh Lett, Mr G Grey Turner, and Mr. C. C Choyce Prof. Hey Groves, retiring from the Council in rotation, is standing for re-election.

# Annotations.

"Ne quid nimis."

## PNEUMOCOCCAL PERITONITIS.

Pneumococcal peritonitis was selected as the subject for the Ingleby Lecture for 1924 by Mr. A. W. Nuthall,[1] and the disease was also discussed at a recent meeting of the London Association of Medical Women's Federation, reported in THE LANCET last week. It is an interesting affection from several points of view. It is arresting in its rapidity of evolution in the fulminating cases, and very often tragic in its inexorable progression towards death in those protracted cases where there seems at least reasonable grounds for anticipating a happy issue. Sometimes the disease appears to be a primary peritonitis, at others it is secondary to a pneumococcal infection elsewhere. The path by which the organism reaches the abdominal cavity in the idiopathic cases is a matter of controversy. J. Fraser and J. E. McCartney[2] brought powerful evidence forward to show that infection takes place from the vagina by way of the Fallopian tubes. They have never seen the primary form in boys in whom the condition seems always to be a sequela to a severe pneumococcal infection elsewhere in the body. They found that in early cases the most advanced changes were at the bottom of the pelvis. Mr. Nuthall does not agree with this view. In two of his patients careful bacteriological search failed to reveal pneumococci in the Fallopian tubes, and he has seen cases in boys where there was no clinical evidence of a visceral lesion to which the disease could be said to be secondary. He believes the peritonitis to be always due to a septicæmia and that the portal of entry is in all likelihood the pharynx. Clinically, pneumococcal peritonitis is characterised by a peculiar absence of the local pain, local tenderness, and local rigidity of other forms. The patient is much more ill than the local symptoms seem to indicate. The bad prognosis would seem to be related with the blood infection; the victim has to overcome a septicæmia of which the peritonitis is only a symptom. The diagnosis is admittedly difficult at first and, the disease being rare, it is unlikely to be prominent in the mind of the practitioner. Some clinicians have been able to demonstrate pneumococci in peritoneal exudate obtained by paracentesis with a fine hollow needle.

The outlook in the disease is so bad that it is not surprising that dissatisfaction with methods of treatment exists. McCartney and Fraser recommend blood transfusion as an accessory measure, and this seems to have proved a powerful weapon of offence. They also recommend early operation as giving the best prospect of cure. Nuthall, on the contrary, thinks operation in the early stage to be not only useless but positively harmful, and compares the condition with acute empyema where delay until frank pus forms has proved to be the better course. He recommends the surgeon to wait until the acute toxæmic stage is passed. Miss Gertrude Herzfeld, at the meeting referred to above, declared that drainage of the lower abdomen was the only possible treatment and that blood transfusion had not proved of much avail. There would, therefore, seem to be room for further investigation in this peculiarly fatal disease.

## A SCIENTIFIC ANNIVERSARY.

This month 25 years ago, writes our Swiss correspondent, Dr. Oscar Bernhard, then medical officer of the Engadin District Hospital at Samaden, made his first experiments with sunlight treatment. He started on purely empirical lines. To him, as an old Engadiner, the method in use amongst the inhabitants of his country of preserving meat and specially bacon by hanging it in the dry air and in the sun was well known. The antiseptic and drying effect of the sun's rays as shown in this method led Dr. Bernhard to try its use on living tissue. The first patient to give him an occasion for this experiment was an Italian with a large open wound which was proving refractory to the usual treatment. On a beautiful day when the sun's rays filled the hospital ward, Dr. Bernhard ordered the wound of his Italian patient to be exposed to air and sunshine. The success of this treatment was a surprise to everyone. The granulations quickly became normal and epithelisation began to take place. Many other experiments followed, the method was scientifically enlarged, and to-day heliotherapy is an established practice. The splendid experiences with the new method in the Engadin were soon tried in other suitable places, especially by Dr. Rollier at Leysin.

## INTRAPERITONEAL INFUSION OF INFANTS.

THE most essential therapeutic measure in the treatment of severe intoxications in infancy consists of the avoidance or removal of dehydration, to which infants are peculiarly susceptible and readily succumb. The administration of fluids by the mouth, except in very small quantities, is usually difficult in the presence of even a moderate degree of toxicity; in many conditions it is rendered uncertain by the vomiting which it provokes or by pre-existent diarrhœa. Intravenous infusion is contra-indicated by the difficulty of the procedure and the damage to veins which may ensue. Rectal enemata are not retained with any degree of certainty; if the rectal route is adopted it is necessary to employ the method of continuous enteroclysis, which has many advocates and is generally satisfactory when the need of fluids is not urgent or prolonged. The absorption of fluids by this method is somewhat slow, and if it is continued for a long period the tube may cause irritation of the mucosa. In cases of severe dehydration—particularly those occasioned by alimentary decomposition—the choice will usually lie between the two methods of subcutaneous and intraperitoneal injection.

The advantages of the subcutaneous route are obvious; it is simple and easy, no question of damage to organs can arise, and the result of any flaw in the aseptic precautions should not be unduly serious. As an emergency measure under unfavourable hygienic conditions it is clearly to be preferred. It has, however, been the experience of many physicians that the results which it yields fall far short of the ideal. It is difficult to introduce more than about 50 c.cm. of fluid without causing local discomfort to the infant, and there may be considerable leakage through the needle track. The rate of absorption is very variable, and in comatose infants may be too slow to be effective. There is little doubt that in all cases where a rapid absorption of a considerable amount of saline is desired, the intraperitoneal route will best meet the requirements. Like most ideal methods, intraperitoneal infusion makes greater demands on the technique, and perhaps the courage, of its employer. The two possible objections to it are the risk of infection and the risk of damaging an abdominal organ. The first is a very real one; the adoption of this method is only justifiable when strict aseptic conditions can be obtained. The second risk appears to have presented less difficulty than might have been expected, and can be obviated by suitable technique. There is undoubted danger of injury if a sharp straight needle is used. Weinburg devised a method for which excellent results have been claimed. He used a needle with a comparatively blunt point, inserting it at a spot corresponding to McBurney's point on the left side. He was able to introduce up to 200 c.cm. of fluid without causing any inconvenience to the infant, and in no case was there any injury of underlying organs. He established the fact that absorption was very much more rapid than in subcutaneous infusion. Aikmann drew attention to the risk of injuring the bladder, and inserted the needle immediately below the umbilicus. A disadvantage of Weinburg's technique lies in the necessity of a preliminary incision of the skin, owing to the bluntness of the needle. This drawback appears to have been overcome by Dr. I. W. Gallant and Dr. R. M. Gordon, who have devised a sharp-pointed curved needle with the aperture in its convex surface. This needle, an account of which was given in THE LANCET of March 27th, p. 000, is passed through a fold of abdominal wall which is drawn up by the finger and thumb. This procedure should prove to be a distinct improvement, and is worthy of trial by all who use the peritoneal route.

[2] Brit. Jour. Surg., 1922, ix., 479.

The benefit obtained by the introduction of saline is established beyond all doubt, but on the question of the efficacy of nutrient infusions there is not the same degree of unanimity. It has been a common practice to add glucose to the saline, and there is experimental evidence that it is absorbed; it is therefore undoubtedly a rational therapeutic measure. The introduction of blood serum has been tried and does not appear to be followed by any undesirable reaction. The improvement brought about by saline infusion alone is so striking that it is difficult to obtain clinical evidence of the extent to which the addition of nutrient material may have participated in the result. Infants tolerate starvation so well, and dehydration so badly, that this question is particularly hard to decide from the results which they yield.

## MASSIVE DOSAGE WITH DIGITALIS.

THE value of the method introduced[1] by Prof. Cary Eggleston, of New York, for the treatment of acute heart failure associated with auricular fibrillation by the oral administration of massive doses of digitalis has not yet been fully appreciated in this country. Why in such cases we should be content to wait several days before achieving the full therapeutic effect of the drug, when it can be obtained with safety in 24 hours, is difficult to understand, unless it be on account of the idea that digitalis is a dangerous drug. Most potent drugs are dangerous if improperly used, but the toxic manifestations of overdosage with digitalis are so well recognised, and the precautions necessary to avoid misadventure are so simple, as to leave no reasonable cause for anxiety. To continue to give digitalis after the heart rate has already reached a subnormal figure, or after bigeminal heart action has set in is to court disaster; but with these clear signs in addition to the gastro-intestinal danger signals as a guide, there is little cause for apprehension. Again, the rate of absorption and elimination of digitalis has been accurately determined, and by allowing an interval of six hours to elapse between doses, any possible danger from cumulative action can be excluded.

In the February number of the *Edinburgh Medical Journal* Dr. A. Rae Gilchrist summarises his experience in 60 cases of auricular fibrillation with heart failure treated by digitalis in massive doses. When the condition of the patient was not urgent, the administration of digitalis was preceded by a control period of rest in bed for several days. The drug was given in the form of the powdered leaf, the full quantity as calculated from Eggleston's formula being divided into three doses given at four-hourly intervals. Dr. Gilchrist states that in most cases there was marked slowing of the heart six hours after the first dose, and that the maximal effect was produced in less than 24 hours, except in those cases where there was much portal congestion, when it was frequently delayed for 48 hours. The slowing effect of the digitalis persisted in most cases for from two to ten days. Dr. Gilchrist points out that the toxic dose of digitalis is very close to the therapeutic dose, but in the rheumatic cases of his series there were no severe toxic manifestations, nor were there any disorders of rhythm apart from occasional extrasystoles. In four patients with normal rhythm, however, auricular fibrillation was induced by the administration of massive doses of digitalis; in two of these the normal rhythm returned spontaneously. Toxic manifestations were more prone to occur where fibrillation was associated with arterio-sclerotic type of myocardial disease. Bigeminal heart action was frequent in this group, and in one case digitalis provoked an attack of paroxysmal ventricular tachycardia. Dr. Gilchrist considers that in urgent cases of heart failure the oral administration of massive doses of digitalis is less dangerous than the intravenous administration of strophanthin. His conclusion that this method of treatment finds its most useful place in cases of auricular fibrillation occurring in the subjects of rheumatic heart disease is in accord with clinical observation elsewhere.

## SURFACE RADIUM-THERAPY.

IN ordinary superficial applications of radium the tissues at a depth receive some of the penetrating gamma rays from radium C which always accompany the beta rays coming away from applicators containing radium or radon in equilibrium with its active deposit of "quick change." In some instances, no doubt, the degree of the reaction of a superficial region thus treated depends upon this gamma-irradiated region, and in the case of human skin reactions it has been shown by Mottram and Russ that if two neighbouring regions of the skin are given equivalent surface intensities of beta and of gamma radiation, that due to the gamma radiation will be more profound in character—the inference being that, although the superficial intensities are the same the structures below the gamma ray surface are more heavily irradiated and contribute to the surface reaction. Perhaps in some skin conditions it would be a good thing if the deeper structures were entirely spared irradiation while a dose is being given to the surface. The method of using the radium active deposit of "slow change" described by Mr. J. P. McHutchison and Dr. W. H. Brown on page 755 of this issue will allow of this being done; for although two of the products used—namely, radium D and radium E—emit gamma rays, they have very little penetrating power; in fact, the combined beta and gamma rays from the preparations used are reduced to a very small percentage of the surface intensity by traversing 8 mm. of tissues. These radio-active preparations may be looked upon, therefore, as giving out radiation only equivalent in penetrating power to very soft X rays and of very weak intensity. Apparently the strongest applicators yet used by the authors gave an erythema of the skin only after seven to eight days' continuous application. It will be of interest to know, as clinical material accumulates, whether the skin reaction is of the same character as results from intense beams of X rays or of ordinary radium sources where the exposures are often a matter of minutes. Recognisable differences would be expected when the intensity is so much reduced, even though the physical dose is identical. Valuable information is given by the authors about their methods of retrieving the active deposit from used radon supplies. This has been a work of scientific economy and will doubtless be made use of at centres where radon in quantities is used.

## SWEATING.

"MAN," said Richard Owen, "is naked and is the only terrestrial mammal in that predicament." He also has an unrivalled power of sweating, and the known and unknown meanings of this capacity are enough to make the study of those rare individuals who cannot sweat a matter of some interest. In the *Journal of Biological Chemistry* (vol. lxvii., 1020, p. 307) Dr. H. B. Richardson describes some calorimetric studies on a case of congenital absence of sweat glands. The boy's practical trouble was that he could not play in summer because he got too hot and had to stop, and he seems to have found out for himself that if he wetted his shirt he could exercise with less discomfort. Detailed examination of his heat production and water elimination under various conditions led to interesting results. The water vapour given off at rest was normal and the evaporation of water accounted for the normal proportion of heat loss. More than two-thirds of the water came from the skin, and it seems clear that considerable quantities can be eliminated through the skin without the intervention of sweat glands, which are apparently not responsible for "insensible perspiration." Under exercise the quantity of heat lost by water vapour was definitely less than normal and the body temperature rose; in hot air also there was no increase of water loss and the temperature rose rapidly. From which it appears that sweat glands have developed to supplement the evacuation of water vapour through the skin; they are not absolutely necessary, and constitute an emergency apparatus which, like some other body mechanisms, becomes progressively less essential as conditions of life and survival become easier.

## CHILD WELFARE IN THE UNITED STATES.

IN an address recently given in Birmingham at a meeting of the Maternity and Child Welfare group of the Society of Medical Officers of Health, and now appearing in *Public Health*, Dr. Ethel Cassie gave an account of a three months' visit to some of the great eastern cities of the United States. The visit was undertaken in order to study the work done on behalf of women and children, whether carried out by States, by municipalities, or by private bodies. The vital statistics for the United States are, on the whole, distinctly more favourable than are those for England and Wales, the birth-rate being higher (22·5 as compared with 20·4) and the general death-rate and infant mortality-rate lower (11·4 and 76 as compared with 12·8 and 77). Dr. Cassie believes the chief cause for this difference to lie in the absence of any serious degree of poverty in the United States, and in the much better standard of housing. The public health service appeared to her to be less well organised than our own, and much less inclusive, except in regard to propaganda. The Children's Bureau at Washington, while possessing its own staff for direct investigations, carries out most of its work through the directors of child hygiene in the various cities and States, the general organisation in each differing very little. In New York the municipal work is on a more limited scale than in our own country, but this is compensated for by the large number of voluntary agencies employing large staffs of highly trained workers and carefully coördinated in order to avoid overlapping.

The conduct of the welfare clinics, of which there are 94 in New York, differs little, if at all, from those in this country, the doctors attending twice a week and advising only on questions of diet and hygiene. The clinics are open to children up to 2 years of age, and not, as here, right up to the age of 5. The midwifery service of New York includes 300 licensed midwives, who attend 26 per cent. of the births. None of these, however, is a trained nurse. The midwives notify ophthalmia neonatorum and puerperal sepsis, but no other notifications are made. Doctors and nurses act as inspectors of midwives. The Maternity Centres Association takes a large proportion of the antenatal work in New York; maternity nurses are provided by this Association for a fee of £5, and the infant is visited up to six weeks of age. An important feature of welfare work in the United States is the establishment of special clinics which appear to have been brought to a high pitch of efficiency. Examples of these are the nutrition clinics, to which children suffering from malnutrition are referred from other centres; the heart clinic in New York, which deals with cases of actual or incipient heart disease in children under 12 years; the posture clinic, in which remedial exercises are taught and carried out for such minor orthopædic defects as flat-foot or knock-knees; psychological clinics for children from 3 years old and upwards; and, in Boston, a neurological clinic, where an elaborate system of muscle training by voluntary exercises has been instituted for infants and young children suffering from birth injuries, the sequelæ of poliomyelitis, and the like. Dr. Cassie draws attention to the somewhat anomalous position of the midwife in the United States. There is no training in midwifery apart from the simple maternity nursing included in the general training of a nurse, and the very existence of the midwife seems in many places, notably in Massachusetts, to be ignored. The maternal mortality-rate, doubtless partly in consequence of this attitude, is everywhere high—e.g., in New York the rate is 6 per 1000 live births, as compared with 3·9 in England and Wales.

Methods of infant feeding varied a good deal in the different places, but apart from the greater use made of thick cereal feeds and lactic acid milk, and the comparatively limited use of dried milk, no great differences were noted from the methods adopted in our own country.

## CRAWFORD WILLIAMSON LONG.

THE Crawford W. Long Memorial Association has just unveiled a statue of Long in the Capitol at Washington, the ceremony taking place on March 30th last, the eighty-fourth anniversary of Long's discovery. It is particularly right that this great man should receive public notice because of the singularly modest and disinterested part which he played in the polemics which have marked discussions upon the introduction of anæsthetics. A sympathetic memoir of him will be found in the first volume of THE LANCET of 1912, written by Dr. Dudley Buxton, consulting anæsthetist at University College Hospital. The memoir fully makes out the claim of Long to be the pioneer of anæsthesia and the first to suggest and employ ether inhalations during surgical operations. Dr. Dudley Buxton says: "While disputants, claiming for themselves or their friends the plaudits due to great discoverers, rent the welkin with their angry cries and clamoured for a material solatium, one man, Crawford Williamson Long, reputed to be actually the first to produce artificial anæsthesia by inhalation of ether, was content to stand aside, calm and dignified, as one who strove to benefit his race while seeking for himself neither guerdon nor worldly honour." In dealing with the question of the rival claims to the honour of introducing ether to the medical profession, the founder of THE LANCET 80 years ago spoke with characteristic vigour: "Many persons have suggested certain sniffings and breathings, and have employed them in private in a few slight cases; but these we may pass by as unworthy of notice—certainly not detracting in the least degree from the praise and honour due to the American originator, whether that originator be Dr. Morton, Dr. Jackson, or Mr. Horace Wells, the last claimant." Only a few weeks after this pronouncement documentary evidence came to THE LANCET substantiating the claim of Horace Wells for the use of nitrous oxide gas for tooth extraction prior to the work of W. T. G. Morton, but at this time the name of Crawford Long was still unknown in England, and indeed was but little known in his own country. His reticence seems to have been due to his perceiving that his methods needed carefully working out, while he held it improper that experiments should be made upon any but suitable patients. When the successes of Wells, Charles Jackson, and Morton became known, with the result that a controversy arose between these three, it appears at the time to have occurred to no one that, while they could settle the second place among themselves, the first place belonged to Long. Dr. Dudley Buxton in his essay supplied a facsimile of a letter from Long dated Feb. 1st, 1842, in which he alludes to being "utterly out of ether" and to intending to use it for anæsthetic purposes in the future. This date is some two years earlier than any date claimed for the discoveries of the other three.

## THE COLLEGE OF NURSING.

THIS week an appeal is being made to the medical profession to help in the endowment of the College of Nursing. There are many who will gladly respond to this appeal because it is an opportunity to express the admiration so widely felt for nurses and their work. None have a better chance of understanding the value and quality of that work than medical practitioners; none comprehend better the conditions of service and remuneration under which nurses still work; none therefore are more anxious to assist in anything that makes for their welfare. To ensure support from the medical profession it is, therefore, only necessary to show that the College of Nursing has a real function and fulfils a real need. When it was founded in 1916 its objects were these: to provide a central organisation for the nursing profession; to raise the standard of training and examination of nurses; to promote the higher education of nurses; and to attract to the profession the best type of woman. There are now 24,000 nurses on the College Register who have complied with the regulations for entry, and the College is recognised by the Ministry of Health as a training centre for the Health Visitors' certificate and is consulted on nursing affairs by Government departments and public bodies. There are 41 branches, seven residential and other clubs, and two convalescent homes at which members may stay at very small charges. Scholarships are awarded for post-graduate work; there is a Loan Fund which has been of assistance in many cases, and there is a special scheme for insurance against sickness and accident. The College's scale of salaries for all grades and branches of the nursing profession is being increasingly adopted by hospitals and employing authorities, and the College has been instrumental in obtaining an amendment to the Unemployment Insurance Act by which all trained nurses and nurses in training are exempted from its provisions, which were a considerable burden upon them. A Student Nurses' Association is a recent development, for the benefit of nurses in training for the general part of the State Register, and the work of the Public Health Section and the Sister Tutor Section are already well known.

The work of the College is steadily expanding. It is governed by a council elected by the members by a postal vote. There is no restriction on membership of the council, and at present there are a number of medical men upon it who are making the appeal referred to. The cost of management, they state, is nearly £5700 a year, and the deficit on each year is considerable, and has to be met out of the General Fund and the interest from the Endowment Fund, which now stands at £67,000. Although the College is in important respects comparable to the colleges of other professions, it is unlike them in that most of them have benefited by the endowments of their founders and by legacies. Apart from the gifts of Viscountess Cowdray, who presented the building near Cavendish-square, and has founded several scholarships and annuities, the College has had to rely on certain earmarked amounts subscribed by the public in the appeal for the Nation's Fund for Nurses and on the donations and subscriptions of its members. Over £35,000 has been subscribed by members and their friends, who have worked extremely hard to get it. By themselves they can hardly hope to secure the further £33,000 which is needed to bring the total up to the £100,000 required, and that is why the appeal is being made to the medical profession. Even the smallest subscriptions will be appreciated; they may be sent to the hon. treasurer, Mr. Comyns Berkeley, or direct to the College, Henrietta-street, W. 1. Largely by subscription in answer to personal appeals by the treasurer about £950 has already been collected, and we hope, if possible, to publish a list of donations in due course in order to further this excellent object.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXVIII.—THE TREATMENT OF LUPUS ERYTHEMATOSUS.

Lupus erythematosus still remains one of the most intractable and capricious of skin diseases. Its name is unfortunate and misleading, as it suggests a relationship with lupus vulgaris, from which it is quite distinct. Of its synonyms the most appropriate is erythema atrophicans, a name given to it by the late Sir Malcolm Morris, which more nearly suggests its nature than that by which it is generally known. Its treatment is best considered under two headings—namely, the treatment of the acute, disseminated type, and that of the more chronic, circumscribed, or discoid type, which constitutes about 80 per cent. of all the cases.

Rational treatment should be based on ætiology. Unfortunately, the ætiology of this disease still remains unsettled. In my opinion lupus erythematosus is not a pathological entity in the true sense, like psoriasis, and due to one specific cause, but is rather a morbid cutaneous condition, of the type of an erythema, which is persistent in character, tends to be succeeded by atrophy, and may be called forth in a predisposed individual by a variety of causes of a toxic or septic character.

Of the predisposing causes, the most important is a delicate condition of the skin, either from hereditary weakness, general morbid conditions, such as tuberculosis, or a weak peripheral circulation, the common situation of the lesions being largely determined by anatomical reasons, such as the stretching of the skin over bone or cartilage. The actual cause is the circulation in the skin of some toxin, either resulting from the impaired action of diseased organs, such as the kidneys or the liver, or possibly originating in some septic focus in the mouth, about the throat or bronchi, or in the alimentary tract. Local influences, such as cold, sudden changes from heat to cold, traumatism, insect bites, or local microbic action, have an important bearing in determining the localisation of the disease.

### *Acute Disseminated Cases.*

*General Measures.*—These cases are so obviously toxic that their treatment resolves itself largely into an endeavour to discover the source of the toxæmia, and to deal with it on general medical principles. The patients are, as a rule, seriously ill, and require confinement to bed. In a fatal case recently under my care at Charing Cross Hospital, the toxæmia was found to be of streptococcal origin, the *Streptococcus longus* being recovered from the throat, which was in a horribly septic condition, and from the urine. After a prolonged illness death took place from acute septicæmia. In another case the eruption appeared in association with Bright's disease, from which the patient died. Other cases have been associated with alcoholism, cirrhosis of the liver, and rheumatism. Where a microbic origin is proved, the microbe being generally a streptococcus, injections of an autogenous vaccine should be tried, but their value is uncertain. Where the actual toxin is not discovered, and an appropriate antitoxin not available, various drugs are reputed to have an antitoxic action. Of these salicin and quinine have given the best results. Salicin should be prescribed in large doses of 15 to 30 gr. three times a day, and in a mixture containing also powdered tragacanth and peppermint water; a few minims of the tincture of nux vomica may be added to counteract the depressing action of the salicin. Quinine also should be given in large doses of 5 to 10 gr. It may be injected intravenously once a week in the form of the hydrochloride, gr. 5, dissolved in normal saline solution 10 c.cm., but there is no great advantage in this method, and it occasionally causes shock.

*Local Treatment* in the acute cases consists of soothing the inflamed skin and endeavouring to reduce the erythema. The scaliness is, as a rule, slight, and requires no special attention. For the reduction of the erythema it is better to use lotions than greasy applications, which are heating; lotions containing lead and ichthyol are of most service. A favourite application consists of the glycerine of the subacetate of lead in water (1 in 8), and the ichthyol may be used in a 3–6 per cent. aqueous solution. The astringent action of the lotion may be increased by the subsequent application of a bland dusting powder. When the acute erythema subsides, and the patches become dry and scaly, a bland zinc cream may be substituted.

In acute cases the prognosis should always be guarded, for although the skin affection may sometimes disappear, either spontaneously or under suitable applications, the underlying toxæmia may sometimes lead to a fatal issue. As a rule, towards the end, in fatal cases, the eruption tends to subside.

### *Chronic Circumscribed Cases.*

*General Treatment.*—In the chronic cases, though the local treatment is of paramount importance, general treatment must on no account be neglected. Any disturbance of the alimentary tract, disease of the kidneys, intestines, or other organs must be carefully sought for and dealt with. The diet should be regulated, and anything which tends to cause flushing, such as alcohol, coffee, rich foods, &c., omitted. A careful examination should be made for any septic focus, such as diseased tonsils, septic gums, or streptococci in the fæces. Benefit has been claimed from removal of the septic focus, and from injections of autogenous vaccines, but in my experience vaccine treatment is apt to be disappointing. Improvement in the lesions may follow a reaction due to an autogenous vaccine, but the reaction is not necessarily specific. Improvement has been claimed to follow injections of sterile milk albumin, and the intravenous injection of a typhoid vaccine.

All sources of local irritation, such as brilliant sunshine, over-heated rooms, cold winds, and violent exercise, should be scrupulously guarded against. Quinine and salicin, especially in cases associated with rheumatism, are also of service in the treatment of the circumscribed lesion, and their value may be enhanced by confinement to bed.

*Local Treatment.*—Since this affection is as easily aggravated as cured by local remedies, it is always advisable to begin treatment in a cautious and tentative fashion, and gradually to increase the strength of the applications according to the toleration of the patient. The two main indications are the removal of the scales and the reduction of the hyperæmia.

The scales should be removed daily, before the application of any lotion or ointment, by washing the lesions with soap, spirit lotion, on a piece of flannel, or, where the scales are particularly adherent, by rubbing in 3 per cent. salicylic acid ointment.

For the reduction of the hyperæmia the time-honoured calamine lotion is a most useful remedy, and its value can be increased by the addition of 2 per cent. of the liquor plumbi subacetatis. Its application not only reduces the erythema, but conceals and protects the patches by leaving a deposit of powder. It should be either dabbed on with cotton-wool or applied continuously for half an hour at a time on lint. Ichthyol, a valuable astringent, can be employed either as a 5 per cent. ointment in vaseline or as a lotion. In resistant patches it may be continuously applied in plaster form. Formalin ointment (5 per cent.) and adrenalin lotion (1 in 1000) are also serviceable, but are liable to irritate a delicate skin. Where the patches are of a fixed, resistant type, and covered by a thick adherent scale, stronger applications are necessary, such as painting the patches with contractile collodion containing 1 per cent. of salicylic acid or the application of a lotion of 10 per cent. resorcin dissolved in spirit, or 6 per cent. oxidised pyrogallic acid paste.

Caustic remedies, such as silver nitrate, carbolic acid, and corrosive sublimate, were at one time largely employed, but are better avoided because their action is so destructive as sometimes to be followed by unsightly scarring. Where the lesions are small good results have been obtained by multiple scarification, but great care and considerable practice are required to avoid scarring. Where patches are on the scalp all that can be hoped is to prevent, if possible, the spread of the diseased process, for, once a patch has occurred, the atrophy associated with it leads to permanent local baldness.

In addition to the chemical methods of treatment, certain physical and electrical methods may be employed, such as ionisation, refrigeration, ultraviolet light, X rays, and radium. Of these ionisation, with a solid zinc electrode, and refrigeration, with carbon dioxide snow, give the best results.

The *ionisation method* is simple. A small piece of lint is saturated in a 2 per cent. solution of sulphate of zinc and applied to the lesion; on this is placed a flat zinc block electrode, of suitable size, which is attached to the positive pole of a galvanic battery; the negative pole consists either of a metal cylinder, covered with chamois leather and dipped in saline solution, which is grasped by the patient, or a large pad held in contact with some part of the skin. A current of 2–5 milliampères is passed for about 15 minutes, the strength of the current being determined by the toleration of the patient. As a result of the exposure the tissue becomes blanched like parchment and remains so for a time varying with the strength of the current. If the exposure be not excessive there will be no subsequent reaction, but if it be too prolonged, or the current too strong, superficial ulceration may result. A single treatment may suffice to cause the involution of the patch, but, as a rule, several are necessary and should be given at intervals of not less than a week.

*Freezing* with carbon dioxide sometimes gives excellent results, especially in resistant lesions, but it must on no account be used where the disease is active and spreading. The applications should not be longer than 10 to 15 seconds, with medium pressure, since, especially in situations where the skin is thin and stretched over bones or cartilage, over-exposure may lead to superficial ulceration and scarring.

*Ultra-violet light* is of comparatively little value. I have found that the patches react more vigorously to the rays than the normal skin, and that, when the reaction subsides, slight improvement may follow, especially in lesions of the fixed chronic type, but I have never known the disease to disappear under this treatment alone, and I have known it to cause spreading.

X rays and radium have also been recommended, but the results from them are disappointing.

J. M. H. MacLeod, M.D. Aberd., F.R.C.P. Lond.,
Physician for Diseases of the Skin,
Charing Cross Hospital.

---

New Sussex Hospital for Women.—At the annual meeting on March 15th of the New Sussex Hospital for Women and Children at Brighton—an institution entirely officered by women doctors—reference was made to the progress of cancer research carried on there in conjunction with work at three London hospitals. Miss Louisa Martindale, the senior surgeon, said that this was the first coördinated work of its kind in the country. Hitherto, cancer research had been done in individual hospitals, but now the same dosage of radium was being used by different surgeons at hospitals dealing with different classes of patients. To continue this promising work was one urgent reason for extending the hospital's accommodation at Brighton. Lady Cooper Rawson said that if an extension was built and a new ward with 30 beds was opened at once, there would still be a waiting-list. The number of in-patients treated during the year was 486, compared with 430 in 1924. Out-patients numbered 2553 as against 2471. The finances showed a sound position, the sum of £683 received during the year as payment for treatment given to members of the Sussex Provident Scheme being one of the main sources of support. The institution continued to pay its way.

# Special Articles.

## THE TUBERCULOUS COW.

CAN tubercle-free herds be kept at a profit and is it worth a farmer's while to keep them? How can the public be educated to demand clean milk? Why has the medical profession done so little to foster the demand? These are some of the questions raised at a conference of the "Grade A (Tuberculin-tested)" Milk Producers' Association held on March 23rd and 24th at the University of Reading.

Most of the problems discussed were primarily agricultural; but the endeavour behind them has been inspired mainly by doctors, and its success or failure is important to the public health. Therefore the opinions and difficulties of those who are trying to get rid of tuberculosis from their cattle deserve the sympathetic consideration of the medical profession.

On the first morning the conference met under the presidency of Dr. R. KING BROWN, medical officer of health for Bermondsey, who commended the effort to supply clean milk as part of the larger campaign for uncontaminated food.

### *Growing Enlightenment of Scotland.*

Mr. J. KIRKWOOD gave an account of what was being done in Scotland. There, he said, as in England, there were five kinds of milk—namely, ordinary commercial, pasteurised, Grade A, Grade A (Tuberculin-tested), and Grade A (Certified). At the end of February, 1926, there were in Scotland 19 producers of Certified milk, 27 of Grade A (T.T.), and 15 of Grade A, and the movement was making rapid progress. Eight of the 11 county institutions in Lanarkshire were supplied with milk of the first two qualities, and in Aberdeen it was provided in all the fever hospitals and welfare centres. These were only two examples out of many, and it was noteworthy that the Milk Designation Order had made the ordinary farmer, and not the pedigree breeder only, take an interest in eradicating tuberculosis. The present names of the grades, however, were most unsatisfactory, as the public could not understand what they meant. Why should not the four safe kinds of milk be called A, B, C, and D? As it was, people naturally supposed Grade A to be the best obtainable, and unscrupulous dealers traded on this. Farmers who had rid their herds of tubercle at considerable trouble and expense were entitled to have this fact intelligibly stated to their customers. They also needed the helpful coöperation of medical officers of health rather than criticism from them.

Mr. J. M. CAIE (Scottish Board of Agriculture) said that ordinary milk in one of the Scottish cities cost 6*d.* per quart; Grade A (T.T.) fluctuated in price, but was usually about 2*d.* dearer; whilst Certified was sold at a flat rate of 1*s.* all the year round. That epitomised the problem The demand for Certified milk was going up faster than the demand for the other grades, because the buyer who once abandoned ordinary milk thereafter insisted on the very best. In Scotland in June, 1925, there were 450,000 cows, and perhaps 1500 of them were giving graded milk. Doctors could do a great deal to stimulate demand, and demand would lower price.

Mr. D. SCOTT (Scottish Board of Health) said that until four years ago people considered one milk as good as another, whether it contained pus, tubercle bacilli, fat, or none of these things. At least the public nowadays knew that there was a difference, and to that extent grading had been a success. The names might not be ideal, but what were the alternatives?

Other speakers regretted that consumers were still so backward that they demanded warm milk in the morning and did not appreciate it properly cooled; and an animated discussion ended with a reply from Mr. KIRKWOOD, who found it hard to believe in the schedule of prices given by Mr. Caie and said that the demand for the higher grades of milk was greater amongst the poor than the rich.

### *The Education of the Farmer.*

A paper by Mr. J. P. BLACKSHAW (Ministry of Agriculture) described the rapid progress of the last half century. British dairying, he said, was certainly not behind that of any other country, and the cause of cleanliness had been helped immensely by practical demonstrations at agricultural shows and farms, by classes for milkers, and by clean milk competitions. Last year there had been competitions in 33 counties in which over 15,000 cows were entered; competitors who were lukewarm at first had often ended by becoming producers of graded milk. All that they needed was a market, and it was the medical officer of health and the sanitary inspector who could do most to find one. Many of them did a great deal—as in Bermondsey, Newcastle, and Leeds—but there were many who did not. In Newcastle a gallon of tuberculin-tested milk was supplied daily for each 350 of the population.

Dr. STENHOUSE WILLIAMS said that in Reading one-sixth of the town's supply was of this kind.—Mr. J. A. HANLEY said that the M.O.H. for Leeds had made some sort of a competitive test obligatory on those who supplied institutions in the city.—Other speakers pointed out how easy it was for the producer to lose his keenness or to neglect personal supervision. He was apt to fight shy of the many rules and regulations, and if his standard did fall he should be gently treated and given every chance to get advice from the agricultural educational authorities of his county. It was a great mistake to take licences away before assistance of this kind had been offered.

The conference passed a resolution urging that this should never be done.

### *The Cost of Eliminating Tuberculosis.*

Mr. V. LIVERSAGE dealt with the expenses incurred in starting a tubercle-free herd and their effect on the price of milk. Proper concrete flooring for the premises and a good water-supply were often heavy items, and he estimated the average loss on each cow that reacted to tuberculin at about £10. Extra labour was needed for the production of Grade A milk, which amounted to about 100 man-hours per cow per year. A number of estimates by farmers put the annual extra cost of keeping a tuberculin-tested herd at an average of £2 5*s.* 3*d.* per cow, and he thought that it usually worked out at between 2½*d.* and 3*d.* per gallon of milk.

Mr. Liversage's figures gave rise to a good deal of discussion. One speaker, drawing attention to the estimated profit of 13*s.* 4*d.* on each cow in the year, pointed out that in arriving even at this meagre figure nothing had been allowed for losses and the cost of labour had been taken at its lowest. The prospect was most melancholy. Another said that if the existing regulations were properly observed, nine farmers out of ten would have to embark on expensive alterations of their premises and the price of ordinary commercial milk would go up accordingly. Not all the expenditure, therefore, should be attributed to the cost of eliminating tuberculosis. All the same, it was obvious that a gallon of Grade A (T.T.) milk cost the producer at least 3*d.* more than a gallon of ordinary milk, and then there was the distributor to be considered as well. It was ridiculous to say that the farmer could do it more cheaply if only there were better management.

### *The Number of Reactors and the Advantages of Removing Them.*

On March 24th the chair was taken by Dr. A. A. MUSSEN (M.O.H. for Liverpool), and the proceedings opened with a paper by Mr. W. L. LITTLE on the value of the tuberculin test to the dairy farmer. Out of 400 animals tested for the first time he had

---

[1] The last four of these are supplied only under licence. Grade A is milk which comes up to a reasonable standard of clean production; Grade A (T.T.) is clean milk from a tubercle-free herd; whilst Grade A (Certified) milk is similar to Grade A (T.T.), but is bottled at the farm to ensure even greater cleanliness.

found that nearly 38 per cent. were reactors. There was thus a good deal of loss to be faced in making a herd tubercle-free. On the other hand, there were definite advantages, for the cows would not be likely to suffer from sterility or mastitis; there would be no wasters; they would not eat so much as those affected by tuberculosis; and there was a growing demand for tuberculin-tested cows which enabled the farmer to sell them at £3 or £4 more per head. The meat inspector of Cork had recently said that 50 per cent. of animals slaughtered in that city were tuberculous, and it was an advantage to be sure that carcasses would not be rejected. Lastly, the tubercle-free cow had a greater expectation of life. No animal once reacting, said Mr. Little, should ever be given another chance. The tuberculin test rarely failed, and then only in animals not actively infectious at the time; and it was to be hoped that British cattle would eventually be freed from tuberculosis as were those of the Channel Islands.

The Secretary of the Association (Lieut.-Colonel C. MADDOCK, I.M.S.) read a paper by Mr. G. P. MALE in which he mentioned other advantages to the owner who got rid of reactors. There was no longer a fear that time and money would be lost owing to seizures of milk alleged to contain tubercle bacilli. No fresh animal, he thought, should be introduced into a herd of non-reactors until it had been tested, quarantined for six months, and tested again by the double method.

Dr. MYER COPLANS (interpreting for Prof. MAZÉ, of the Pasteur Institute) said that only 7 per cent. of Normandy cattle were found to react. They were more in the open air than English animals, but perhaps the Shorthorns of England were particularly susceptible?—Mr. LITTLE replied that tuberculosis was a disease of the sheds, and that was why the disease was so prevalent in England. In Canada only some 12 per cent. reacted.— Mr. CUMBER pointed out that this low figure perhaps applied only to those under 3 years old. Of young animals in this country probably not 5 per cent. would react, and it was quite erroneous to suggest that the Canadian cattle were more healthy than the English. —Dr. RALPH PICKEN (M.O.H. for Cardiff) said that he would put the number of tuberculous carcasses in Cardiff slaughterhouses at not more than 5 per cent. It depended on age and sex; the percentage amongst milch cows would be about 10–15 per cent.—A speaker from Devonshire remarked that not more than 2 per cent. of the cows in his county reacted.

Prof. G. H. WOOLDRIDGE gave an address of great interest, in the course of which he said that in introducing outsiders into the herd a medium course was desirable. No animal should be admitted straight away unless it came from another tubercle-free herd; one or two months' isolation was needed in case there was infection as yet undeveloped. Most of the troubles of owners were caused by cows being given the benefit of the doubt when there was one, and although there were border-line cases, no risks should ever be taken. No one breed of cattle showed special susceptibility to tubercle, but those which came from herds long immune were the first to succumb to infection. This was true also of human beings.

Many other speakers continued the discussion. Captain ROSS GRANT said that experience in Queensland showed that environment had very little to do with the infection. Arbitrary statements about percentage of reactors conveyed little; in Queensland it was found that less than 4 per cent. of bullocks reacted, but the figure for breeding cows (kept until the age of 8 or 9) was 30 or 40 per cent. Yet none of them had ever been near a shed, and they had been out in the sunshine all their lives. Housing had far less effect than was generally assumed. The real difficulty in this country was the disposal of the reactors. Obviously they could not be destroyed, and the consequence was that they were simply transferred to other herds. There was only one solution of the problem—to have two kinds of milk—namely, tubercle-free milk and *boiled* milk.

### *A Standard for Tuberculin.*

At the suggestion of Prof. R. S. SETON a resolution was passed urging that a standard of potency and preparation for veterinary tuberculin for diagnostic purposes be laid down and that its use be restricted to medical and veterinary practitioners. The conference considered the present state of affairs exceedingly unsatisfactory.

### *The Growing Consumption of Graded Milk.*

Mr. T. A. HOLE (Ministry of Health) said that the grading of milk was started by the Food Ministry in 1918, but had made little progress until 1922. In 1923 more exact standards were introduced and by the end of that year there were 144 licensed producers and 800 licensed distributors. At the end of 1924 there were 224 producers, and the number was steadily growing as the market grew better. There were now 200 tuberculin-tested herds and there were licensees in all but nine English counties, by far the largest number being in Berkshire, where the National Institute for Research in Dairying had been established since 1912. Altogether some 3,700,000 gallons of Certified and Grade A (T.T.) milk were now being produced annually, and the average consumer was now beginning to realise that the keeping of milk depended on its quality.

Dr. KING BROWN described the growth of the clean milk movement in Bermondsey. Practically all the milkmen there now sold graded milk at 1*d.* a pint more than the ordinary, and the borough was providing tuberculin-tested milk in welfare centres, and as extra nourishment for the tuberculous. At first there had been some talk of municipal distribution, which had had the effect of spurring on the milkmen to very efficient service. More than 1400 families in Bermondsey were now receiving Grade A (T.T.) milk and the standard was very high indeed. A count of 200,000 organisms (the legal standard) was unheard of; a count of 30,000 (the standard for Certified milk) was very rare indeed, and things had gone so far that a Bermondsey milkman whose milk went up to 10,000 would very likely be cautioned. A market had been gained simply by education and propaganda. Lectures were given in clubs, factories, associations, and schools, and a cinema film showing the production of clean milk (from the cow to the kitchen) was exhibited at street corners. There were also leaflets and picturesque handbills. An electric sign displaying some doggerel verses about milk had been most successful and the words had been eagerly learnt by all the children in the locality, who sang them with enthusiasm. The result was that the parents of every child in Bermondsey could not help knowing something, at any rate, about milk.

Dr. PICKEN said that no Grade A (T.T.) milk was on sale in Cardiff, and it was useless to encourage its use until there was an available source. Some 330 gallons of Grade A milk (about 3 per cent. of the whole) were coming into the city daily, but unfortunately about 100 had to be sold as ordinary milk. He had found that some 60 per cent. of commercial milk in Wales came up to the Grade A standard, though the figure was lower in summer. Cleanliness had steadily increased till last year, but since then there had not been improvement. One of the difficulties was that the public expected expensive milk to contain more fat, and they were disappointed when it did not. Graded milk producers must keep well below the legal standards of bacterial content, for the consumer was very critical; and they ought to be especially careful not to use cattle food which would give an objectionable flavour to the milk. Unfortunately the price of common milk was rising and it would be increasingly difficult to get people to pay more for a specialty.

### *Efficient Cooling.*

Mr. W. A. HOY gave an account of his observations on the bacterial content of milk as it reached the distributor. What was needed, he said, was more efficient cooling at the farm, with subsequent cold storage at a local depôt before despatch to the retailer.

Mr. W. Davies advocated the use of brine coolers on the farms. It was not sufficient that milk should be clean; it must also be cool. Once the public understood about graded milk, he said, there would be no difficulty in finding a market, and what was really needed to-day was an intensive campaign amongst members of the medical profession.

An official dinner was held in the hall of the University on March 23rd, at which Prof. Mazé replied to the toast of "The Visitors," proposed by Mr. S. R. Whitley. Dr. Stenhouse Williams, of the National Institute for Research in Dairying, represented the University of Reading, to which a charter has just been granted, and replied on its behalf to a toast by Mr. A. T. Loram. On the afternoons of March 23rd and 24th visits were paid to a number of farms in the neighbourhood of Reading and to the National Institute for Research in Dairying.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *Powers and Duties of Coroners.*

A SELECT Committee of the Senate of the Irish Free State is at present considering a Coroners Bill, and recently heard evidence from Mr. J. J. Horgan, coroner of Cork, who spoke on behalf of the Coroners Association. The salaries of coroners, he said, were totally inadequate to the office—the more so, as they had to pay all their travelling expenses and also had to pay their deputies. A coroner, he thought, should be able to dispense with a jury, especially where an inquest was held in the house of a poor family, on whom the tramping in of a dozen men had a depressing effect. He suggested, and the Committee accepted the suggestion, that it should be a statutory obligation on the Civic Guard to report to the coroner in cases where death took place without medical attendance. The coroner should have the right to order the exhumation of a body without seeking the consent of the Minister for Justice. The question of the coroner having the right to call in a pathologist and pay him a proper fee was one of great importance. At present, moreover, he was empowered to allow no more than 5*s.* for the exhumation and reinterment of a body. He could not give a witness expenses beyond 2*s.*, and even then could only give such expenses to a poor person.

### *Wards for Paying Patients.*

At the annual meeting of the Corporation of the Royal Victoria Hospital, Belfast, several speakers urged that a paying department should be provided for middle-class patients and the idea was received very sympathetically by the large audience. For a long time the medical profession in Belfast has been greatly interested in the project; its importance and even its urgency are generally recognised. Opinion seems to favour the provision of such a department in connexion with existing general hospitals, rather than the erection of a special and independent hospital, but the question is still open to discussion. The Royal Victoria Hospital is in the fortunate position of possessing about 19 acres of ground, situated in a favourable position, and offering ample opportunity for the erection of a block of paying wards. Seven acres of this has been given to the hospital during the past year by the City Corporation. The hospital has been going ahead in many directions and the extensions and additions which have been in progress for nearly three years are now practically complete. They comprise two new units containing 80 beds, three new operating theatres, two new lecture rooms in the extern department, increased accommodation for the ophthalmic, venereal, and dental departments, a new mortuary, and a new nurses' home. The approximate cost of these additions and improvements is estimated at £120,000. Most of the new additions are already in commission and the formal inauguration will take place in a few weeks.

## SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

### *The Training of Natives as Doctors to their Own People.*

THE question of a medical training school for natives is occupying the minds both of officials of the Union Government and of those more directly concerned with native education. Foremost amongst the latter are the directors of the South African Native College, near Lovedale, Cape Colony. So far there has been no provision for training a native man or woman in the practice of medicine, for, although we have now two universities which give a complete curriculum and confer a South African degree, neither of them will admit a native to its classes. The Government is not unsympathetic towards the demand of the native for medical training, and the matter was referred to the Hospitals Committee whose report was published last year. Its findings were as follows:—

> "Your Committee is convinced that there is scope, and a distinct need in the native territories, for native doctors, working as far as possible under European supervision. The standard should be the same as for European medical practitioners, and any licence to practise should be restricted to native areas. Your Committee therefore recommends that the question be further investigated by Government, particularly in regard to the cost of such a proposal."

These recommendations have now been acted upon, and a special committee of inquiry, to consist of seven members, has been appointed to go into the proposal for the establishment of a training college for the training of natives in medicine and public health. The committee has been carefully chosen, and represents the Cape Town University, the Native Affairs Department, and the Health Department of the Union. The various provinces have each their own representative. Meanwhile the South African Native College, Fort Hare, has started courses in physics, chemistry, botany, and zoology with the object of saving one year's study overseas for those of their students who are taking their medical training in Great Britain, where all the medical schools are open to them.

The need for native practitioners amongst their own people is abundantly evident. At the present time there is an average of one hospital bed to every 1500 of the population. The Europeans are provided for in the ratio of one bed to every 400 persons, about half that of England, and less than one-third of the ratio obtaining in the United States. Government provides for the treatment of natives as part of their civil service, and it is intended that native practitioners should work under them as the Indian hospital assistant works under the civil surgeon in India. Throughout the Union to-day the district surgeon has an area of 100 miles and more to cover in the native territories. If he could be provided with two or three hospital assistants in charge of small branch hospitals the lot of the sick native would be greatly alleviated, and the spread of the knowledge of sanitation and personal hygiene would also become possible from these centres.

### *Hospital Deficiencies within the Union.*

The reports of the Hospitals Inquiry Commission, published last year, is a strong indictment of the whole hospital system of the Union. The Provincial Councils of the four Provinces are responsible for the upkeep and administration of all hospitals and dispensaries within their borders. After full inquiry the Commissioners were unanimous in condemning the existing system, and strongly advocated that all health and hospital administration should come under the sole control of the Union Government. They based their recommendation on the following facts. The out-of-date equipment and inadequate accommodation of nearly all the hospitals; lack of suitable provision for maternity cases, sick children, and cases of venereal disease; the neglect of early cases of tuberculosis and lack of accommodation for advanced cases; and the failure to provide adequately for the chronic sick. In this connexion the report says:—

> "There are only three chronic sick hospitals in the whole of the Union—in none of these has provision been made for chronic sick children—a dire necessity all over the Union."

Finally the report points out that there are, in the whole Union, no adequate dental services for either children or adults; no neurological department at any hospital; no institution for the treatment of crippled children; no provision for medical treatment of such children as the medical inspectors of schools may recommend for treatment. A motion is now before the Union Parliament that the Government should give effect to the report of the Hospitals Inquiry Committee as soon as possible, the main recommendation being that the hospitals should be taken out of the control of the Provincial Councils and handed over to the Union Department of Health.

### *Defective Transvaal Children.*

A report on the medical examination of schoolchildren in the Transvaal shows the existence of a large proportion of physical defects, most of which are attributed to parental neglect, direct or indirect. Of the 15,000 children examined by authority of the medical inspector of schools, 7500 were found to be suffering from minor defects. Malarial children were being robbed of Government quinine supplies by their parents; there were about 75 per cent. of dental defects, and 800 children needed attention for ear, nose, or throat. The children were all treated free under the clinic system established at Johannesburg for children of indigent parents.

The South African Medical and Pharmacy Bill, long held over, is to be re-introduced into the Union Parliament at the end of the present session.

Dr. S. G. Campbell, who died on March 12th at the age of 65, was one of Durban's leading citizens. He was at one time president of the local medical council, and was responsible for the foundation of the Technical College.

Dr. Wallace Haworth, entomologist to the Administration of Southern Rhodesia and late acting director of the laboratory at Dar-es-Salaam, East Africa, died on March 14th as the result of injuries received in a motor accident.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *A Filter-passing Virus in Tuberculosis.*

IN pursuance of their work on the virus of tuberculosis Dr. Fernand Arloing and Dr. A. Dufourt, of Lyons, have published some observations on a child born prematurely at the seventh month whose mother suffered from advanced pulmonary tuberculosis. This child was isolated at once and was given every care, but died at the end of a month after losing a fifth of its weight. On examination no obvious tuberculous lesion was found, though there were a few tubercle bacilli in the mesenteric glands. A filtered extract of the principal viscera had no effect when injected into a guinea-pig, but subcutaneous injection of a filtered extract of the mesenteric glands produced tuberculisation of the animal leading to emaciation and death. There is a remarkable similarity between this observation on a human being and previous experimental results; they obviously have an important bearing on the inheritance of tuberculosis. According to Dr. Arloing and Dr. Dufourt there is in the new-born a special pathological condition, not yet understood, due to a filterable virus of tuberculosis being passed through the placenta. Some of the obscure wasting conditions, hypotrophies and atrophies of childhood ought probably to be placed in this group.

### *Medical Practice by a Chiropodist.*

A well-known Parisian chiropodist has just been had up for illegal medical practice. The tribunal learned that he had been using a scalpel and caustics in the treatment of warts, and adjudged that the use of these agents was the prerogative of medical men. The complainants, a local association of doctors, were accordingly awarded 300 francs damages, and a fine of 100 francs was inflicted.

### *Diabetes and Insulin.*

Insulin has entirely altered the prognosis of diabetes, and its late results are as remarkable as its immediate effects. Prof. Marcel Labbé estimates that half the subjects that he has treated would have died in coma but for insulin. Unfortunately, tuberculosis is common among diabetics in France and insulin has no effect in hindering its development. Furthermore, those who are treated with insulin, although greatly helped, are still very delicate and run the risk of complications; they have to be kept under careful observation, and none of them can be considered really cured. Most patients, Prof. Labbé considers, show a progressive aggravation of the diabetic process, which calls for larger and larger doses of insulin; but the evolution of the disease is made considerably slower.

### *New Academicians.*

The two vacant seats at the Académie de Médecine have been filled by the election of Prof. Georges Dumas and Prof. A. Couvelaire. Prof. Dumas, who was born in 1866, occupies the chair of experimental psychology at the Sorbonne and the chair of pathological psychology at the Institute of Psychology. During the war he rendered good service as physician to the Neuropsychiatric Clinic and since then he has been on several important missions to America. His books on the intellectual states, grief, joy, and laughter, and on the confusional amnesias have been much appreciated. Prof. Couvelaire was born in 1873 and is professor in the Obstetric Clinic of the Faculté de Médecine at Paris, in which position he succeeded his father-in-law, Prof. Pinard. The Académie des Sciences has elected Dr. Jean Charcot, son of the famous neurologist of the Salpêtrière. Dr. Charcot studied medicine but afterwards became an explorer, and has published valuable scientific observations on the South Polar regions.

### *Production and Sale of Pacifiers Prohibited.*

Prof. Pinard, who is well known as a champion of puériculture, has succeeded in persuading the Chamber of Deputies to prohibit the manufacture and sale of the *sucette* (dummy or pacifier) on the grounds that this device deforms the mouth, introduces infection, and may easily prove fatal when aspirated into the larynx. Its baneful effects have been discussed more than once during the past year at the Faculté de Médecine, but hitherto the conditions of the labour market have prevented any active steps, for the manufacture of these dangerous utensils serves to support a large community just outside Paris. The Bill was approved mainly because of a stirring appeal for reduction of the French child and infant mortality. An interval of three months has been allowed for the readjustment of the industrial concerns affected.

The French Society for the Encouragement of National Industry has just awarded its highest honour to the League of Red Cross Societies, in recognition of the importance of the League in the peaceful coördination of international interests.

About 100 Danish doctors have been visiting France and are now cruising in the Mediterranean. During their stay at Paris they opened a Danish nurses' home which is the first headquarters established in France for the Danish medical and nursing professions.

A series of lectures and demonstrations, called Journées Médicales de Paris, is to be held at the Grand Palais from July 15th to 19th, inclusive. Among those who will give lectures and demonstrations are Calmette, Putti (of Bologna), Bensaude, Sicard, Balthazard, Madame Curie, and others. The membership fee will be 50 francs, and particulars may be had from the Secrétaire-Général, Journées Médicales de Paris, 18 rue de Verneuil.

The French National Congress on Hygiene will be held at the Pasteur Institute, Paris, during the second fortnight of October. The subjects announced provisionally for discussion include the French immigration problem, the preservation of food by cold, and the part assignable to official hygienists in the anti-tuberculosis campaign.

# Public Health Services.

## REPORTS OF MEDICAL OFFICERS OF HEALTH.

### THE FIRST REPORT FOR 1925.

Dr. A. T. Nankivell's first report for Plymouth is also the first report which we have received for the "survey" year of 1925. He is able to record valuable work, since he took up his appointment, in the coördination of the public health service and in the institution of close coöperation between the various departments. This is shown graphically in a table. Dr. Nankivell indicates many of the needs of Plymouth, and it will be interesting to see how many of these needs his council has been able to provide before the advent of the next "survey" year of 1930.

The following are some of the principal statistics for the year 1925 Population, 211,078; birth-rate, 18·1; death-rate from all causes, 12·2; death-rates per 1000 of the population, from tuberculosis 1·06, from cancer 1·80, from respiratory diseases, with influenza, 2·8; and death-rates per 1000 births, neonatal mortality 30, infant mortality 63, maternal mortality from childbirth 4·7. Dr. Nankivell deals fully with the aim of the health service, the public health organisation, the history and natural, geological and social conditions of his area. Among the advantages of Plymouth he instances the large amount of bright sunshine (the record for 1925 was 1705·5 hours as compared with an average of 1660), and the fact that, owing to geological features and contours, the somewhat heavy rainfall (39·11 inches in 1925, or about 3 inches above the average) is speedily drained off. A chart shows that though the total infant mortality has been reduced from the neighbourhood of 100 to the neighbourhood of 60 during the last ten years, the neonatal mortality has remained almost stationary. In spite of natural advantages, pneumonia and bronchitis show a heavy death-rate, and Dr. Nankivell hopes before next autumn to be able to supply the doctors in the Three Towns with a vaccine which will give some protection from these complaints. Compared with other garrison and seaport towns, Dr. Nankivell thinks that Plymouth is relatively a sober borough. The ship used as a small-pox hospital has been sold to a ship-breaker, and negotiations are in progress for the use by the borough of the small-pox hospital of the Plymouth rural district.

Dr. Nankivell would like to see every medical member of his staff engaged in some research work, and during the year some work has been done with regard to the silica contents of dust from different towns and as to the use of the Dick serum in the treatment of scarlet fever. The two gathering-grounds of the water-supply are moorland and well protected from contamination. The water is very soft but has no action on lead. Bacterial analysis shows the presence of *Bacillus coli*, and Dr. Nankivell suggests that these are brought on the feet of seagulls from the sewage outfalls or from one of the tips. One would have thought the "droppings" of the seagulls a more likely explanation. About two-thirds of the practitioners of Plymouth who replied to a questionnaire as to the prevalence of goitre expressed the opinion that the condition was very prevalent. This is somewhat surprising in view of the generally held opinion that proximity to the sea and the iodine borne by the sea-spray act as protectives. Dr. Nankivell condemns the dumping of the refuse in the sea and the use of refuse tips in two localities. He would like to see all the refuse dealt with by a proper destructor or pulverising plant.

Many of the houses in the Three Towns, built more than 100 years ago, can only be dealt with adequately by reconstruction schemes, and three such schemes have been submitted to the Ministry of Health for their approval. The council of Plymouth have utilised the section for repairing houses in the default of, and at the cost of, the owners to the extent of £5515. Dr. Nankivell points out that there is no remedy in the case of thriftless and unintelligent persons who take no care of the houses in which they live. In Holland, he says, bad tenants are taken to a segregation camp and kept there under discipline until they are reformed—with admirable results. The shortage of houses has led to overcrowding and the herding of more than one family in houses only intended for one family. Altogether the Plymouth council have erected 1101 houses for the use of the working classes. During 1925 186 new municipal houses were made ready for tenants, and at the end of the year 192 were in course of construction. Apart from municipal houses 200 new houses were completed and 286 were under construction at the end of the year, in addition to 40 houses built by the Astor Trust. The present public abattoir is quite inadequate, and a report made at the end of the year states that "from the point of view of public health and decency this is not a suitable site for our abattoir and a real effort should be made to move this objectionable trade to the outskirts of the borough."

An extensive outbreak of food poisoning occurred at the workhouse in April. Three hundred persons out of a total population of 750 were affected, fortunately with no deaths. The chief cook was found to be a carrier of bacilli resembling *B. suipestifer*. The use of Dick-Dochez serum for severe cases of scarlet fever gave encouraging results at the hospital, and immunisation against diphtheria was successfully practised in the case of outbreaks at two institutions during the year. Dr. Nankivell is optimistic as to the possibility of protecting all infants from diphtheria, thus enabling the diphtheria wards to be closed. A scheme is under consideration for an orthopædic hospital at Swilly for the treatment of crippling from rickets, tuberculosis, and poliomyelitis. For the treatment of non-pulmonary tuberculosis Plymouth is at present entirely dependent upon outside institutions. A sanatorium is also needed for intermediate and advanced cases of tuberculosis in females. Antenatal clinics are only working on a small scale. Thus there were 3832 births and 812 mothers attended the antenatal clinics. Up to April, 1925, there was only one school dentist. Since that date there have been two, but Dr. Nankivell calculates that two school dentists are only able to do about one-third of the work which ought to be done The school medical service has assumed control of the orthopædic clinic and all arrangements for supplying remedial apparatus. The school medical officers visit the clinic weekly or oftener and the consulting orthopædic surgeon once a month. The two open-air schools have accommodation for about 150 each; but many improvements are overdue at both schools. Oysters are cultivated within the jurisdiction of the Plymouth Port Sanitary Authority. The Yealm beds at Steer Point are used for relaying purposes, but the shell-fish in the Tamar and Lynher are liable to sewage contamination from Saltash and are only allowed to be sold for re-stocking purposes.

The report concludes with a number of interesting tables and a copy of a leaflet on cancer, which has been widely circulated in Plymouth.

### Encephalitis Lethargica in Manchester.

A valuable monograph on sleepy sickness by Dr. W. St. Clair McClure accompanies Dr. R. Veitch Clark's recently issued report on the health of Manchester for the years 1923 and 1924. In 1919 10 cases were notified, and in the following years 31, 19, 9, 36, and 244. The 36 cases notified in 1923 were widely distributed over the city, and no connexion could be traced between them. Sixteen of them proved fatal. During December, 1923, four cases occurred in four districts. In January, 1924, there were 21 cases in 15 districts, and thereafter the whole city was involved. Persons of all ages were attacked, but the incidence was heaviest under the age of 20. The sex distribution was nearly equal, 129 patients being males and 115 females. The average case fatality was about 20 per cent.; the death-roll is not yet complete. No occupational influence could be traced, although unfavourable environment showed some effect. There was nothing suggestive in the way of illness among the 1207 family contacts, except perhaps two cases of hiccup. No association could be made out with influenza; an outbreak of this occurred after the encephalitis had subsided, and there were ten cases of influenza among the 1207 encephalitis contacts. Influenza did not invade the households attacked by encephalitis, and no correlation was shown between the two diseases during the past five years in Manchester. An epidemic of hiccup preceded the encephalitis epidemic of 1924. The attacks of hiccup lasted from three to ten days without other symptoms, except drowsiness in a few cases. With two exceptions the households attacked by encephalitis were not affected by hiccup. Further, hiccup was not a common symptom of the encephalitis patients, and was only noted in eight of the notified cases. There were no definite multiple cases in a household, but in seven cases another member of the family had previously suffered from suspicious symptoms. The following was the percentage frequency of certain symptoms:—

| | Per cent. | | Per cent. |
|---|---|---|---|
| Initial vomiting .. .. | 10 | Paralysis of one or more cranial nerves .. .. | 40 |
| Initial headache .. .. | 36 | Double vision .. .. | 44 |
| Pronounced lethargy .. | 70 | Nystagmus .. .. | 10 |
| Insomnia and delirium .. | 30 | Initial choreic twitchings | 31 |

The fundus oculi was examined in 58 patients; in one case there was engorgement of the papillary veins, in the remainder nothing abnormal. Diplopia was the outstanding feature at the onset in a considerable number, and in some cases diplopia and some drowsiness were the only symptoms. The actual notifications received were 282, in 38 of which the diagnosis was subsequently revised as follows: Influenza, 5; typhoid, 1; tuberculous meningitis, 5; cerebral abscess, 2; cerebro-spinal fever, 1; chorea, 2; tonsillitis, 2; broncho-pneumonia, 4; muscular rheumatism, 2; gastritis, 3; anæmia, 2; senility, 2; and others, 7. As a rule the diagnosis was unmistakable. In doubtful cases examination of the spinal fluid was of value in excluding meningitis. It is still too early to determine the final result of the 1924 cases, but of the 50 cases notified in 1920 and 1921 28 have died; 5 are totally incapacitated and becoming completely helpless; 4 are able to do housework only; and only 13 are able to follow their employment or attend school, recovery being complete in 7 of them.

### INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 27th, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 178 (last week 189); scarlet fever, 1586; diphtheria, 1005; enteric fever, 46; pneumonia, 1183; puerperal fever, 45; cerebro-spinal fever, 6; acute poliomyelitis, 1; encephalitis lethargica, 37; dysentery, 0; ophthalmia neonatorum, 119. There were no cases of cholera, plague, or typhus fever notified during the week.

*Deaths.*—In the aggregate of great towns, including London, there were 7 (2) deaths from enteric fever, 121 (49) from measles, 9 (3) from scarlet fever, 66 (4) from whooping-cough, 47 (16) from diphtheria, 38 (11) from diarrhœa and enteritis under 2 years of age, and 136 (27) from influenza. The figures in parentheses are those for London itself. The notified deaths from influenza number the same as last week. The number of deaths from measles is the highest recorded for the quarter.

Influenza in Glasgow.—67 deaths from influenza were reported in Glasgow during the week ended April 3rd, as against 24 and 7 in the preceding weeks; also 60 more deaths from respiratory diseases than in the preceding week. The public health authority is providing for the isolation of many of the severe cases of influenza.

# The Services.

## ARMY MEDICAL SERVICE.

*Assistant Director of Hygiene.*—Lt.-Col. and Bt. Col. P. H. Henderson, R.A.M.C., relinquishes his appt. at the War Office.

### ROYAL ARMY MEDICAL COLLEGE.

*Professor.*—Lt.-Col. and Bt. Col. P. H. Henderson, R.A.M.C., vice Bt. Lt.-Col. J. A. Anderson (vacated).

### ROYAL HOSPITAL, CHELSEA.

*Deputy Surgeon.*—Capt. G. S. McConkey, R.A.M.C., vice Lt. J. G. E. Vachell (vacated).

## ROYAL ARMY MEDICAL CORPS.

Lt.-Col. and Bt. Col. H. E. M. Douglas, from R.A.M.C., to be Col., vice Col. F. F. Carroll, to half pay.

The undermentioned Majs. to be Lt.-Cols.: H. H. J. Fawcett, vice Lt.-Col. P. H. Falkner, to retd. pay. J. D. Richmond, vice Lt.-Col. and Bt. Col. H. E. M. Douglas (promoted).

### ARMY RESERVE OF OFFICERS.

Maj. C. Cassidy ceases to belong to the Res. of Off. on account of ill-health.

### TERRITORIAL ARMY.

Capt. O. H. Mavor resigns his commn., and is granted the rank of Maj. Lt. R. M. Savege to be Capt. (Prov.).

## ROYAL AIR FORCE.

Flying Officer A. Dickson is granted a permanent commission in this rank.

## INDIAN MEDICAL SERVICE.

Temp. Lts. to be temp. Capts.: Ram Chand Gaulatia, Chuni Lal Katial, Ram Mansoor, Santosh Kumar Ganguli, Samuel Mufty, Amar Nath Chopra, Chuni Lal Bhola. V. A. Edge to be Lt.

Capt. Saravanamuthu Thambiah relinquishes his temp. commn.

Sussex Provident Scheme.—The growth of the scheme during 1925 was described at the annual meeting at Brighton on March 20th as extraordinary. The number of groups had increased during the year from 177 to 229, and the number of subscribers from 9955 to 12,428. At the end of 1924 the number of dependants coming under the scheme was 15,306, making the total 25,261, and at the end of 1925 dependants numbered 18,573, making the total 31,001. The total increase was thus 5740 in the year. Other figures given by Major P. A. S. Crawley, the chairman, equally testified to the success of the scheme. In-patients in 1925 cost £5272 and out-patients £1104, a total of £6376; 843 members obtained free special in-patient treatment for 14,058 days, and 2705 members obtained free special out-patient treatment for 12,966 attendances. The number of in-patients was 224 more than in 1924, and the number of out-patients 815 more. The money given to the hospitals was £6376 as against £5501 in 1924, and since the scheme was inaugurated in 1922 it had paid £16,164 to the hospitals. Major Crawley did not think the hospitals could afford not to support the scheme. Generally speaking, the hospitals were very keen, and wished to do everything in their power to support it, but unfortunately a good many omitted from their annual reports any appreciation of the work of the collectors and committee. Although the scheme was run on business lines, it was not a commercial undertaking, and there was no profit to anybody except the hospitals who got the money and the workpeople who got the treatment. The costs of administration were extremely low (£534), and the hospitals had received 81 per cent. of the total cost of their members. That might not have been as much as the executive at one time hoped, but it was as much as any hospital could expect. Subscription to the scheme was very low, and if they could pay over four-fifths of the cost the hospitals had nothing to complain of.

## DIABETES, A RECOVERABLE DISEASE.

*To the Editor of* THE LANCET.

SIR,—My experience with four cases of diabetes mellitus in private practice may be of interest in connexion with the question raised in your issue of March 27th by Dr. G. H. Percival as to what recovery is possible in this disease. Though the cases are few in number, they have been under observation since 1924. Further, these patients have not been kept in bed at any time, but have continued their normal activities, so that the factor of muscular work cannot have influenced their sugar tolerance.

The principle I have worked on from the first has been the same as that practised by Dr. Percival—namely, physiological rest to the damaged pancreas—but I have got a step further and aimed at maintaining the patient for long periods in a state bordering on hypoglycæmia. After ascertaining by a 24-hours fast and a ladder diet that the patient is unable to utilise fully a diet of 1000 calories without glycosuria, I put the patient on an adequate diet of 1000 calories or so, and commence injections of insulin. I start with 5 units twice a day and increase the dose steadily, till slight hypoglycæmic symptoms appear. I then maintain the dose at that level. After a period of time varying with each patient, it is found that the hypoglycæmic symptoms become more pronounced. The dose is then diminished unit by unit, always waiting for constant and fairly pronounced hypoglycæmia to appear before lessening the dose. I continue this system until a minimal dose of 4 units, two hours before the principal meal, gives rise to symptoms. I then discard insulin and keep the patient on a regulated diet. Subsequently, if no sugar reappears in the urine, the diet is allowed to approximate to the normal. All patients are, of course, ordered to carry sugar whilst having insulin and instructed to eat some if muscular weakness appears as a symptom of hypoglycæmia. Slight symptoms are disregarded.

The following are abbreviated notes of the cases.

CASE 1.—Female, aged 41 In February, 1924, acute inflammation of maxillary antrum occurred and patient was unable to spare time for more than drainage of antrum through canine fossa under gas. Drainage maintained by vulcanite plug. Glycosuria discovered in May, 1924 Specific gravity of urine 1035. Hard work was a necessity and a diet of 1800 calories was required in consequence Insulin started in May and during June and July 40 units of insulin twice a day were required to produce hypoglycæmia. This was a great inconvenience and expense. In August chronic discharge from antrum ceased completely and plug was therefore removed and sinus allowed to close In September 20 units of insulin only were required to produce hypoglycæmia. Insulin stopped in July, 1925 Glycosuria has remained absent ever since. Blood-sugar in July, 1925 Fasting, 0·120 per cent.; one hour after 50 g. of glucose, 0·197 per cent., two hours after, 0·110 per cent

CASE 2.—Female, aged 30 Glycosuria discovered in July, 1924. Not controlled by diet. Blood-sugar: Fasting, 0·130 per cent; one hour after 50 g. glucose, 0·222 per cent; two hours after, 0·225 per cent. Ten units of insulin b.d. was found sufficient to cause hypoglycæmia. In March, 1925, insulin was stopped Blood-sugar: Fasting, 0·110 per cent, one hour after, 0·178 per cent.; two hours after, 0·158 per cent Has remained free from glycosuria ever since.

CASE 3.—Male, aged 30 Glycosuria not controlled by diet October, 1924, insulin 10 units b d required March, 1926, insulin stopped Has remained free from glycosuria up to present time

CASE 4.—Male, aged 71. Had had diabetes for over six years accompanied by neuritis. Both knee-jerks were absent In October 1924, hypoglycæmia induced by 17 units b.d. Knee-jerks returned by end of the month. In April, 1925, 13 units only were required once a day. Owing to an attack of agonising tic douloureux, treatment of diabetes became disorganised, and a new start had to be made in July with 20 units b d. Blood-sugar then was: Fasting, 0·173 per cent; one hour after 50 g. glucose, 0·210 per cent.; two hours after, 0·210 per cent. In January, 1926, his dose was 8 units once a day Blood-sugar was: Fasting, 0·163 per cent.; one hour after, 0·250 per cent.; two hours after, 0·175 per cent. I still hope that insulin may be discarded eventually in this case.

These four cases are entirely unselected. In none of them could the glycosuria be abolished by diet alone. In all of them great improvement in sugar tolerance resulted from the treatment, and in three of them insulin has been discarded and the glycosuria has not returned, though the patients enjoy a satisfying and varied diet. Incidentally, I think I have proved that it was justifiable to ignore the numerous warnings from eminent authorities that appeared in the medical press in 1924 on the subject of insulin dosage and the dangers of hypoglycæmia.

I am, Sir, yours faithfully,

Bridlington, March 31st, 1926. P. D. H. CHAPMAN.

## THEORY AND PRACTICE IN RELATION TO THE TREATMENT OF CANCER WITH LEAD.

*To the Editor of* THE LANCET.

SIR,—Since the meeting at the Medical Society of London on March 22nd hopes have been expressed by my friends that I would refute this or that statement after having had an opportunity of looking up the papers concerned, for, at the time, not having them with me, I had to be content with a general disavowal or an apology. I am, however, extremely loth to say anything more. Dr. Adami has already shown[1] how perverted certain criticism was, and how easily refuted. What he has said applies to nearly every adverse statement made in regard to our methods, and to the alleged "sloppiness" of our publications. Nor shall I be so ungracious as to ask for the correction of the one or two small verbal mistakes made in the excellent accounts of the meeting given by the medical reporters present. It was better that the accounts of such a meeting should be compiled by independent recorders rather than based on the usual abstracts sent in by the speakers.

There is, however, one matter to which, with Mr. Duncan Fitzwilliams's concurrence, I should like to refer. It will be remembered that Mr. Fitzwilliams made great play with a vivid description of a letter he said he had received from me—a letter which he thought illustrated bad faith on my part. In my reply, I ventured, from memory, to deny ever having dictated such a letter, and I suggested what I had probably written. Mr. Fitzwilliams, it will be recalled, then rose in his place and contradicted me. Thirty-six hours later I received the following letter from him:

'I am so sorry and I apologise most humbly for having contradicted you in what you recollected of having written to me

"Last night I asked my secretary to look up your letter but left the house in a hurry and did not take it with me—it was lying on my desk when I came home and it is exactly as you said, you have put my name down for notification for sometime perhaps in April. I visualised your letter as something quite different and having got it in my head I have not the vaguest idea with what I have mixed it up—I am indeed sorry.

"Let me add my congratulations on the success of your meeting last night I know perfectly well from what I had heard that you had met a not too friendly audience, and that you carried them completely with you must be a very great satisfaction to you.

"I shall look forward with great pleasure to seeing you in April."

This is the letter of a gentleman. Nevertheless, such mistakes should be avoided. Confident assertions and reassertions may produce an impression on an audience which is not always removed by a declaration of the truth at a later date. I feel sure that when Mr. Fitzwilliams comes to see us in a few weeks' time, so honourable a critic will realise and confess that we have neither magnified the dangers and difficulties, nor over-estimated the results we have obtained. Be this as it may, he will receive a cordial welcome, as have all those who during the last few years have visited us.—I am, Sir, yours faithfully,

---

Liverpool, March 28th, 1926. W. BLAIR BELL.

## EMETINE IN THE TREATMENT OF HEPATIC ABSCESS.

*To the Editor of* THE LANCET.

SIR,—Having operated on 167 cases of hepatic abscess and seen many others, I should like to comment on Dr. Hodson's letter with Dr. Manson-Bahr's reply thereto which appeared in your issue of March 27th. Dr. Hodson divides his letter into sections:—

1. *Pathology*—and therein states that "People obsessed with the pyogenic abscess idea find it difficult to believe that the absorption of the contents of 'hepatic abscesses,' large and small, is possible." In my experience it is possible, but rarely occurs.

2. *Diagnosis.*—I do not think it is generally accepted that aspiration is necessary for the diagnosis of a liver abscess. Dr. Hodson goes on to quote a case in which death occurred from rupture of the abscess two hours after treatment was begun. Presumably aspiration was not employed; if this trifling operation had been performed would not the rupture with fatal results been prevented? I have a vivid recollection of a case which came into hospital at the end of a long and hot morning's operating which I postponed until the next day; unfortunately the abscess ruptured in the night with fatal results. I still feel that I was guilty in not at least giving the patient a chance by aspirating at once.

3. *Treatment.*—There I am absolutely opposed to Dr. Hodson's views; in my previous papers I think that I have proved that aspiration plus emetine does cure in "the quickest, the most certain, and the most humane way possible," as opposed to emetine alone.

Time after time I have had a patient on the table in pain and suffering the utmost discomfort, and after an injection of cocaine performed a painless aspiration and watched the patient's drawn expression gradually disappear as the pus was withdrawn. It is astonishing, too, what an amount of pus may be found with few physical signs. My experience is against the statement that 25 per cent. of the abscesses are multiple.

I agree that emetine, gr. i., on 12 successive days is not the best way of administering the drug, but my views in detail on the subject can be found in THE LANCET of Nov. 15th, 1924, p. 1008. My experience is also against the statement that the larger the abscess the easier is it to cure with emetine alone; in this respect I entirely concur with Dr. Manson-Bahr's reply—in fact, with all of it.

I am, Sir, yours faithfully,
E. OWEN THURSTON, F.R.C.S.,
Lieut.-Col., I.M.S.

Budleigh Salterton, March 28th, 1926.

## THE GENERAL MEDICAL COUNCIL AND SPECIALISTS.

*To the Editor of* THE LANCET.

SIR,—The suggestion contained in Mr. Joseph Griffith's valuable letter appearing in your issue of March 20th that the General Medical Council should insist on a standard of training and attainment for specialists and should keep a register of such specialists, is one which—as regards the registration of specialists—I advanced in your columns two years ago.[1] I then pointed out that the accessibility of such a register to the general public was a matter of prime importance, the point on which I laid special emphasis being the difficulty under present conditions that the public experience when they desire to consult a specialist, as they have no data on which to form an opinion except their recognition of names that have appeared in the lay press as having been in attendance on some distinguished patient. I drew attention to the fact that, whereas as regards the majority of diseases many of the public may perhaps be content to accept the advice of their family doctor or of friends in their selection of a specialist, that this is not true of sufferers from venereal disease, who are loath to seek such advice, with the result that they are driven either to attend a public clinic or to seek the advice of a chemist in a district where they are unknown. Owing to this difficulty in obtaining the names of reliable specialists the patient often postpones his visit to a doctor until much valuable time has been lost. An authoritative register of adequately tested specialists would, therefore, be of special value to sufferers from venereal disease and appears to be urgently required.

I am, Sir, yours faithfully,
H. WANSEY BAYLY.

Harley-street, W., March 26th, 1926.

## FACULTY OF SPEECH.

*To the Editor of* THE LANCET.

SIR,—With reference to the annotation in your issue of Feb. 6th, p. 299, on a paper of mine dealing with the Intuitive Capacity of Children to Understand Spoken Language, I am of the opinion that the word "instinct" as applied to the faculty of speech is a misnomer, an instinct being an elementary impulse incapable of further analysis, whereas the faculty of speech is a complex mental process capable in part of analysis and consisting of at least five factors:—

1. The capacity to hear spoken sounds.
2. The capacity to recognise the component words of phrases and sentences.
3. The ultimate capacity to comprehend the meanings of spoken sounds.
4. The capacity to store in the memory both the sounds and meanings of words.
5. The capacity not only to reproduce words—i.e., to articulate—correctly, but to use them in their correct senses.

The question how speech is acquired by infants and children depends therefore largely upon the solution of the third of the factors mentioned above—i.e., how the meanings of words are comprehended by them.

The writer of your annotation states that "meaning is indicated or suggested to the child *in some manner other than speech.*" With regard to verbs of "action" and to the names of objects it is easily understood how meaning is indicated or suggested, but concerning the bulk of the matériel of a language—viz., conjunctions, prepositions, moods, tenses, &c.—which are purely mental concepts, meaning cannot be indicated either by sight or by "action." The meanings of these must therefore be suggested either from without or from within. If from without the suggestion must be in the nature of "thought-transference" or telepathy. That this may in part be the way in which very young infants comprehend the meanings of words I am not prepared to deny; but I am of the opinion that it is not sufficient wholly to explain the phenomenon of the comprehension of spoken sounds. I have therefore put forward the hypothesis in my article that such suggestion comes from *within*, and that part of the "speech centre" of children is endowed with the capacity of comprehending the intended meanings of spoken sounds.

Some years ago a series of communications appeared in your columns[1] regarding "Calculating Boys." The analogy between the calculating faculty as found in these boys and the faculty for comprehending the meanings of spoken sounds, as found in infants and children, is very close, the calculating faculty being found also, as a rule, in childhood only and disappearing before adolescence From the details of this calculating faculty as given in THE LANCET and by F. W. H Myers,[*] it is obvious that the faculty must be a purely automatic function of a localised area of the brain. This being so, the hypothesis that one of the areas of brain concerned with the faculty of speech is endowed with the analogous capacity for comprehending the intended meanings of spoken sounds is not, I submit, either improbable or unreasonable

---

[1] THE LANCET, 1922, ii., 1090, 1154, 1205, 1259, and 1312; and 1923, i., 58.

I am, Sir, yours faithfully,
J W TOMB

Asansol, Bengal, India, March 11th, 1926

*⁎* *The controversy resolves itself into the question* whether speech is to be regarded as an 'instinct" or as a "capacity' or group of capacities. It is both If instinct is, as it is generally defined, an impulse to act in certain ways in the presence of certain stimuli, then speech is entitled to rank as such, the provocative impulse being the speech of others—hence the echolalia of the young child and the dumbness of the deaf Or, if we say this is only imitation, is not imitation an instinctive tendency? No one will deny, however, that more than instinct is involved, and that the full appreciation and command of language depends upon general intelligence and upon *certain specific capacities.* We are not convinced that a specific capacity to comprehend the meanings of spoken words is a sufficient explanation of the phenomena Dr Tomb describes, if, indeed, it explains them at all Dr Tomb admits that the meaning of certain nouns and verbs is acquired by "means other than speech," but surely he does not seriously contend that the acquirement of the meaning of prepositions or conjunctions is explained by a mere capacity They must be taught or suggested in some way A capacity may explain language, but certainly not *a* language. Investigations into the vocabulary of young children have shown that the correct understanding *and use of prepositions* and conjunctions is a late acquisition, as compared with that of nouns and verbs, they are dependent upon a further development *of intelligence* *Dr* Tomb's suggestion that this capacity may be analogous to the calculating faculty of young prodigies is scarcely supported by the comparative rarity of the calculating faculty and its disappearance at adolescence. The difficulty felt by the adult is not that of comprehending meaning but of retaining the new words. It is difficult to see how Dr Tomb's theory explains the easy acquirement of several languages by young children in India in contrast to the relative difficulty felt by adults.—ED L.

## NOTES ON CURRENT TOPICS

### *The Coroners Bill.*

THE Coroners (Amendment) Bill, which was read a third time in the House of Lords on Monday, March 29th, was introduced in the House of Commons on Tuesday, *March 30th and read a first time*

### *The Protection of Animals Act, 1911 (Amendment) Bill*

On Tuesday March 30th, Dr DRUMMOND SHIELS introduced the Protection of Animals Act, 1911 (Amendment) Bill which was read a first time.

### *Easter Adjournment.*

The House of Commons adjourned for the Easter recess on Thursday April 1st, until *Tuesday, April 13th*

## HOUSE OF COMMONS

THURSDAY, MARCH 25TH.

### *Poor-law Infirmaries.*

Mr BROAD asked the Minister of Health *if he would give* a list of towns of upwards of 100 000 inhabitants showing the number of Poor-law infirmaries in each and giving figures showing the average number of patients the number of *medical staff and the number of nursing staff* —Mr NEVILLE CHAMBERLAIN replied: The following statement gives the information desired so far as it is available (omitting London):—

| Towns or urban districts with over 100,000 inhabitants and union (U) in which comprised. | Separate Poor law infirm. in union. | Av No patients year ended 31/3/25 | Medical staff. | Nursing staff |
|---|---|---|---|---|
| Birkenhead (U) | 1 | 466 | 4 | 90 |
| Birmingham (U) | 2 | 1107 | 15 | 302 |
| Bolton (U) | 1 | 480 | 3 | 86 |
| Bristol (U) | 1 | 684 | 6 | 81 |
| Croydon (U) | 1 | 425 | 3 | 88 |
| Tottenham (Edmonton U) | 1 | 827 | 11 | 170 |
| Leeds (U) | 1 | 980 | 5 | 153 |
| Leicester (U) | 1 | 461 | 3 | 87 |
| Manchester (U) | 1 | 478 | 3 | 140 |
| Newcastle-on Tyne (U) | 1 | 555 | 5 | 111 |

* No information.

In the unions comprising the following towns or urban districts having over 100 000 inhabitants, there are no separate Poor-law infirmaries for the reception of the sick: Blackburn, Bradford (Yorks) Brighton Burnley, Cardiff, Coventry Derby Gateshead, Huddersfield, Kingston-on Hull Middlesbrough Norwich Oldham, Plymouth, Preston, *Rhondda Saint Helens Southend-on-Sea South Shields,* Stoke-on Trent Sunderland, Swansea, Willesden, and Wolverhampton.

Mr BROAD asked the Minister of Health what number of beds were available for patients in Poor law infirmaries *in London and the* provinces, respectively; and how many beds on the average were vacant during the periods of October to March and April to September, respectively —Mr NEVILLE CHAMBERLAIN replied I regret that this information is not available in exactly the form suggested by *the question I hope* that the statement below will give sufficient information for the hon. Member's purposes:—

*Separate Infirmaries Provided by Boards of Guardians in London and the Provinces*

| — | Separate Poor-law infirm. | Accommodation Jan 1st 1925 | Inmates Jan. 1st, 1925 | Av No inmates year ended March 31st, 1925 |
|---|---|---|---|---|
| London | 27 | 10,330 | 13 990 | 13 611 |
| Provinces | 30 | 17,517 | 11,804 | 11,835 |

### *Service Men and Tuberculosis.*

Dr. VERNON DAVIES asked the Prime Minister whether he was aware that during each year a number of officers and men were invalided out of the Army, Navy, and Air Force suffering from pulmonary tuberculosis; that as a rule it was impossible accurately to determine whether the disease was attributable to the conditions of service or not; that the large majority of cases were decided as not being so attributable and consequently received no pension on account of their disability; and that the only money the men received during their prolonged and debilitating illness was from the National Health Insurance, which was inadequate for the purpose; and whether he would consider the possibility of instituting a form of insurance (compulsory or otherwise) for officers and men in these services against this disease, so that on being invalided out of the services for this disease they might receive a pension adequate for their needs until recovery or death.—Mr. CHURCHILL (Chancellor of the Exchequer) replied: I am advised that the answer to the first and third parts of the question is in the affirmative. As regards the second part of the question, the disease is prevalent throughout all classes and all occupations, and unless there is evidence that the patient has been exposed to abnormal conditions of service to which he would not have been subjected in ordinary life, the disease cannot be held attributable to the service. Every case has therefore to be considered on its merits. As regards the fourth part of the question, the non-effective benefits granted to officers in non-attributable cases are considered sufficient, having regard to their ages and length of service. In attributable cases these grants are increased by supplementary allowances which in cases of total disablement amount to £100 a year. In addition grants in aid of sanatorium expenses are made so long as the officers remain on the active list. Men invalided for tuberculosis are entitled to the benefits of the National Health Insurance Acts, and, in addition, to a pension for life if they have 11 years' service (or 10 in certain cases). In attributable cases the pension based on service is supplemented by a further allowance in respect of the disablement. Where the service amounts to less than the above periods a gratuity is payable. As regards the last part of the question, I do not think it would be practicable to differentiate between tuberculosis and other non-attributable diseases, so far as insurance is concerned.

### *Vermin in the Hinckley Workhouse.*

Sir CHARLES OMAN asked the Minister of Health whether he was aware that at a debate of the Hinckley Board of Guardians the statement was made by the master that the rooms inhabited by the tramps were verminous, and men's shirts, after they were washed, were in the same condition, and that he could do nothing more at present; that the board discussed the purchase of a calefactor and a disinfector and the prospect of obtaining a loan from the Ministry for such purchase; and whether he would grant the loan and spread over the time for repayment as long as possible, so as to encourage these and other guardians to take vigorous steps to prevent the spread of vermin.—Mr. NEVILLE CHAMBERLAIN replied: Plans for the provision of improved casual accommodation in this union are at present under consideration, and sanction has been given to the raising of a loan for ten years for the purpose referred to in the second part of the question.

### *Milk and Dairies Draft Order.*

Mr. LAMB asked the Minister of Health whether his attention had been called to the serious delay which had taken place in connexion with the printing and circulation of the Draft Order proposed to be made under the Milk and Dairies (Consolidation) Act, 1915, and to the consequent difficulty of making its contents known to the great number of persons affected; and if he would extend the time during which representations might be made to him with regard to the provisions of the Draft Order.—Mr. NEVILLE CHAMBERLAIN replied: I am aware of the delay referred to by my hon. friend and I shall, in view of it, be pleased to extend the time during which any representations may be made to me as to the Draft Order until the *end* of April.

### *Dispensers in the Army.*

Sir PHILIP DAWSON asked the Secretary of State for War how many men in the British Army held the army qualification of dispenser; and how many of these army dispensers were actually employed at the present time in dispensing duties.—Sir L. WORTHINGTON-EVANS replied: The number of soldiers serving in the Royal Army Medical Corps who hold the army qualification of dispenser is 352, of whom 193 are employed on dispensing duties.

## MONDAY, MARCH 29TH.

### *Deaths and Sickness among Coke Oven Workers.*

Mr. STEPHEN MITCHELL asked the Home Secretary the number of deaths and the number of cases of illness which occurred annually among those working at coke ovens and furnaces; the average length of time employees were able to stand this form of work; and if this employment was classed as a dangerous occupation.—Sir W. JOYNSON-HICKS replied: I regret that the information asked for in the first two parts of the question is not available. As regards the last part, employment at coke ovens has not been treated as an unhealthy occupation. No complaints of sickness among coke oven workers have been received, and it would appear from the mortality tables published in Part IV. of the Supplement to the Seventy-fifth Annual Report of the Registrar-General for England and Wales (pp. 2 and 31), that the mortality among coke burners in the three years 1910–1912 was considerably below the average for the population generally.

### *Medical Needs in East Africa.*

Mr. BENNETT asked the Secretary of State for the Colonies whether he was aware of the representations now being made by the British Social Hygiene Council for a percentage of the East African Development Loan to be allocated to urgent medical needs in those areas in which development works were to take place; and whether this purpose came within the scope of the East African Development Loan.—Mr. AMERY replied: I am aware of the representations referred to. I must not anticipate either the advice of the Committee which I have appointed to consider the services to be met out of the loan or the decision of Parliament as to the provisions of the legislation which is required. It is, I think, generally recognised that provision should be included for capital expenditure on medical research, but I doubt whether it would be desirable to spend the loan money on recurrent services which are, or should, normally be met from annual revenue.

### *Indian Transferred Services.*

Mr. WALLHEAD asked the Under Secretary of State for India what subjects, services, duties, and responsibilities had been transferred by the Secretary of State for India from the India Office to the Office of the High Commissioner for India since the establishment of the latter office; and what consequential changes of staff had taken place.—Earl WINTERTON replied: The staff of the High Commissioner for India now deals (among others) with the following subjects, which have been transferred to his charge from that of the Secretary of State in Council: Indian students, leave-pay, pensions and passages of civil officers, recruiting in United Kingdom of all civil officers except those of the all India services, and a few special appointments, and opium and dangerous drugs. In all cases transfer of work has been accompanied by transfer of staff formerly employed upon it in the India Office, the total number so transferred since the formation of the High Commissioner's office being approximately 500.

### *Assistance for Blind Persons.*

Captain FRASER asked the Minister of Health how many local authorities had made, or had under consideration for early application, schemes which gave blind persons in their areas an assurance of a minimum income equal to or greater than that provided under the scheme proposed to be inaugurated by the Hull Town Council under the Blind Persons Act, 1920.—Sir K. WOOD replied: Twenty-two authorities have made, and 12 authorities have under consideration, arrangements similar to those under consideration in Hull for the augmentation of the incomes of blind persons to a fixed amount, but my right hon. friend is not aware of any case in which it is proposed to give an assurance of a minimum income equal to or greater than that contemplated by the Hull Town Council.

### *Experiments in the Utilisation of Whey.*

Mr. AMMON asked the Minister of Agriculture the objects of the lactose factory erected by the State at Haslington in 1919–20; and the progress realised in the discovery of new processes.—Mr. GUINNESS replied: The object of the lactose factory was to discover an economic process for the utilisation of whey. In the opinion of those directly concerned with the experimental work this object has been achieved. The process is described in a monograph recently published by the Ministry.

## TUESDAY, MARCH 30TH.

### *Miners' Industrial Diseases.*

Mr. CHARLES EDWARDS asked the Secretary for Mines whether he was aware that miners' nystagmus and other diseases to which miners were liable were not included in the Third Schedule of the Workmen's Compensation (Consolidated) Act, 1925; and as Section 41 did not preclude payment of compensation for any diseases not mentioned in the above Schedule to that Act, what steps he proposed to take to make clear the position of persons contracting these diseases after May next.—Sir WILLIAM JOYNSON-HICKS replied: The Act of 1925 was a purely consolidating measure, and the reason why miners' nystagmus, beat-knee, beat-elbow, and beat-hand are not specified in the Third Schedule to the Act is that they are not specified in the corresponding Schedule to the Act of 1906. The right to compensation, however, in respect of these diseases remains unaffected. They were brought within the Act of 1906 by Orders made by the Secretary of State under Section 8 of that Act, and it is expressly provided in the 1925 Act that any Orders in force under a previous Act shall continue in force and have effect as if made under the 1925 Act. Subject, therefore, to the provisions of any future Orders, the new Act will apply to these diseases in precisely the same way as the present Acts. The position is quite clear, and I do not think it should be necessary for me to take any special steps in the matter.

### *Cost of Health Services.*

Mr. HERBERT WILLIAMS asked the Minister of Health the total amount provided by the Exchequer for national health insurance and for all other health services in the financial year 1913–14 and in the Estimates for 1926–27.—Sir K. WOOD replied: The total amounts provided by the Exchequer for national health insurance and for all other health services administered by the Ministry of Health or its predecessors (excluding grants out of the assigned revenues and the cost of central administration) in the periods specified are as follows:—

| | Expenditure *1913–14.* | Estimates, *1926–27.* |
|---|---|---|
| For National Health Insurance— | £ | £ |
| Statutory proportion of benefits (other than sanatorium benefit) and cost of administration . | 1,709,535 | 5,427,000 |
| Special grants towards cost of medical benefit and administration . .. .. | 1,529,500 | NIL |
| Statutory proportion of sanatorium benefit .. | 100,000 | |
| For other health services (including in 1926–27 grant in lieu of sanatorium benefit) . .. | 183,134 | 3,076,100 |
| Total .. .. | £3,533,480 | £8,503,100 |

### *London University and Bloomsbury Site.*

Dr. LITTLE asked the Chancellor of the Exchequer what communication had been made to the Duke of Bedford with regard to the reversion to the vendor of the Bloomsbury site, which had been declined by the University of London because of the impossibility of fulfilling the conditions of Mr Fisher's offer of 1920.—Mr. CHURCHILL replied: Notice has been served on the solicitor to the Bedford Estate offering the re-sale of the Bloomsbury site to the Duke of Bedford pursuant to the provisions of Clause 7 of the Conveyance of March 23rd, 1921.

## WEDNESDAY, MARCH 31ST.

## THE ECONOMY BILL.

### *State Contribution to Health Insurance.*

The House went into Committee on the Economy (Miscellaneous Provisions) Bill, Mr. JAMES HOPE in the chair.

On Clause 1, which reduces the State contribution to the national health insurance scheme,

Mr. HARNEY moved that the clause be postponed. He said that there could be no doubt that this clause very intimately affected the approved societies. Not only did it alter the whole of the financial structure of the scheme, but it altered the benefits that they would be able to pay. This Bill could not possibly be completed before Easter and there was in his submission the strongest possible ground for this clause, which went to the root of the mischief as the approved societies saw it, not being dealt with until the societies had had an opportunity of considering it.

Mr. P. HARRIS seconded the amendment. He said this clause was the most controversial in the Bill. They were bound to criticise it word for word and line for line so long as the various friendly societies were not satisfied. Those societies were all meeting at Easter with this terrible cloud over them and they were bringing pressure on Members on all sides of the House to attack this clause. They were reasonable people, and it was possible that they might be placated. The Minister of Health might be able to make some concessions which would ensure the smooth passage of the clause. He thought, therefore, that the Minister would be wise if he agreed to postpone this clause to the end, so that he might have time to consult all the parties concerned and get the coöperation of the friendly societies instead of their hostility.

Mr. NEVILLE CHAMBERLAIN (Minister of Health) said that he was bound to resist the proposal. No valid reason had been advanced why the clause should be postponed. They were not dealing here with an ordinary amendment of the Insurance Act; they were dealing with an Economy Bill. It was well known that they could not fix the date for the opening of the Budget until they had disposed of this Bill. As regarded concessions, he had no reason to suppose that if on this Bill suggestions were put forward which did not affect vital matters that he would not be able to make concessions.

Mr. LLOYD GEORGE said there was no doubt at all that this was a question which the societies ought to have time to consider. The House of Commons was now adjudicating on a proposition which was never before the country at the last General Election. It was a new change—a change which even the Chancellor of the Exchequer did not anticipate last year.

Replying to further discussion,

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that this clause had been before the approved societies for three weeks. They had been given as much information in regard to it as had been given in connexion with any proposal that had been before the House for some time. There was an actuarial report, and there was an exposition of the clauses of the Bill. Explanations were fully given. Immediately the present Bill was introduced the Minister of Health called together the Consultative Council representing all the approved societies in the country. That meeting was held, he believed, on the very day when the text of the Bill was available to members of the House. His right hon. friend made a statement to that gathering and explained at considerable length the provisions of the Bill. After having considered the proposals at length, carefully and seriously, the Consultative Council came to the conclusion that while they had no objection to Clause 2 they were opposed by a majority of 28 to 6 to the proposals of Clause 1. There was no proper reason, however, why Clause 1 should be postponed. If at the conferences up and down the country at Easter any practical suggestions were put before his right hon. friend, he would be glad to consider them and they could be dealt with at other stages of the Bill.

After further discussion Mr. J. H. THOMAS moved that the Committee "Report Progress." This was defeated by 227 votes to 121, and the discussion on Mr. Harney's amendment was resumed.

Some time later, Mr. CHAMBERLAIN moved the closure which was carried by 232 votes to 127. The motion to postpone the clause was then negatived by 229 votes to 129.

### *The Question of a Broken Pledge.*

The Committee then proceeded to a long discussion on the general principle of Clause 1 on an amendment moved by Mr J. H. THOMAS, the object of which was to prevent the clause being operative until the next General Election. The right hon. gentleman gave numerous quotations from speeches delivered during the passage of the original Insurance Act in 1911 to support his contention that pledges were given to the approved societies with regard to the amount of a State contribution, which were being broken in the present Bill. He said he wished to contrast the treatment that the approved societies had received from the Government with that which the societies had meted out to the Government. References had been made in the debate to the difficulties experienced owing to the threatened trouble with the doctors. Immediately the facts were put to the approved societies they took the responsibility of saying: "The State is in a difficulty; we will help them out with their burden." At the same time the societies were promised a Royal Commission, and now having helped the State, having provided the money and taken over a liability which they need not have taken over, and which if they had forced the hand of the State Parliament would have had to take over—although the societies had acted in this way at the time of the ultimatum issued by the doctors—this was the way that they were being repaid! He asked the Committee to ponder before they took this step which the Government asked them to take. What was the amount of money to be saved? Just under £3,000,000. The great Economy Bill provided £10,000,000 all told, every copper of which came from the sick, the maimed, and the children, and, worst of all, from the unemployed. Although he fully anticipated the fate of his amendment, he knew the ultimate verdict and judgment would be determined not inside but outside the House.

Mr. LLOYD GEORGE said he had great pleasure in supporting the amendment moved in a very powerful and convincing speech by Mr. Thomas. The Minister really responsible for this outrage was not present to defend it. The real artful dodger was not there, and it had been left to the Minister of Health to defend something which he thought in his heart he must feel to be rather indefensible. He was told that it was a question of economy. If the country were really hardly pressed and it was a question of £2,000,000 or £3,000,000 to extricate it from its difficulties, no one believed that the 15,000,000 workmen in the insurance societies would decline to consider it. But now when the national burdens had decreased—they were down by

£200,000,000 or £300,000,000 since 1920—and when the benefits under this scheme had matured, for the Government to say that they would take away this £2,800,000 was not a very reputable thing to do. The Government might have consulted the societies, but they had not done so. Was it worth while in order to save ½*d.* in the £ on the income tax to deprive workmen of the benefits to which they were looking forward for the last 10 or 15 years, and especially at a time when there was so much industrial trouble brewing? *Would it not cost* the Exchequer a great deal more in the end? If the Government had suspended the building of even one cruiser they would have been more than able to supply the money required over the next three years, and in that period the country would be recovering. When prosperity returned and the revenue returns went up, the Chancellor of the Exchequer would be able to meet the liability, and probably to decrease the taxation very considerably.

### *The Minister of Health's Reply.*

Mr. CHAMBERLAIN said that they had been again reminded that this was a question of a bargain and of a breach of faith. He had not been able to understand what was exactly the bargain which Mr. Thomas and Mr. Lloyd George said that the Government had broken. Under the original scheme the contribution was 7*d.* and the benefit 7*d.* Under the Act of 1920 the contribution was raised to 10*d.*, but the benefits were also raised to 10·7*d.* As a result of the Pensions Act the contribution was reduced to 9*d.*, but the benefits were reduced only to 10½*d.* Therefore, if they made no alteration in the State contributions people would actually be receiving benefits worth 1½*d.* more than the contributions. Until they had a report of the Actuarial Committee and the report of the Royal Commission it was impossible to say what reconstruction was possible and feasible. But it was quite a mistake to suppose that this reconsideration and review of the whole scheme for national health insurance arose solely out of the need of economy. It would have had to be reviewed in any case. The original scheme was merely experimental. The scheme had been amended in all sorts of ways, but this was the first time that there had been a full review of the whole scheme as they found in the report of the Royal Commission. In any case they were bound to review the financial basis of the scheme and make some alteration in it. The investigation showed that there was a margin in the contributions over and above what was required to provide the benefits under the existing category. The margin was greater than was necessary even to provide the additional benefits distributed already. The Royal Commission while disclaiming any duty to say whether or not that margin should be taken by the State—a question on which they were not competent to speak—showed there was a margin, and on the assumption that it was not to be taken by the State they made certain recommendations. The first of those recommendations was that the full cost of medical benefit should fall on the funds of the approved societies. That was, of course, embodied in the present Bill. There would remain a further sum which the Royal Commission recommended should be used in a certain way for additional insurance benefit. That was the sum which under this Bill the Government were taking because of the needs of the country. The needs of the country were not going to be satisfied by £2,800,000 a year, but in taking a general view of the financial needs of the nation and looking round to every department and every source to see what could possibly be saved and what reductions in expenditure could be made they would not have done their duty if they had neglected to consider the report of the Royal Commission and the opportunity afforded them to take some of the margin. He took any charge of a breach of faith as a serious matter, and he made no distinction between pledges made by himself and those given by other Ministers who had preceded him; and if he thought that in these proposals any charge could fairly and properly be brought against them of breaking their pledges certainly he would be no party to them. He did not deny that pledges were made in 1911, but he contended that they were keeping those pledges. The Government were not raiding surpluses; the surpluses were entirely untouched by the Bill. After this Bill was passed the societies would still continue to reap the benefit of their thrift and their careful and economical management; but the report of the actuary and the report of the Royal Commission showed without any shadow or vestige of doubt that the surpluses which had been accumulated to such a gigantic figure had been due in the main to extraneous causes which were not to be described as due to anything that had been done by the societies, but arose mainly out of the extra rate of interest which they were enabled to earn. The rate was 3 per cent., which was taken into account by the actuaries when they were making their calculations as to the appropriate rate of contribution by the State in the original scheme. Now that the rate of interest was 5 per cent. instead of 3 per cent. it was reasonable that they should review the whole situation. He denied the statement that the Government had not treated the societies fairly. Various Governments had taken upon themselves the burden of the extra cost of diseases estimated at £10,000,000 and on account of minor charges another £5,000,000. He might also mention other things such as provisions for the improvement of the public health, &c., provisions for the relief of tuberculosis, sanatoria, *maternity and child welfare schemes, and so forth. All* those meant that to the extent they had been successful they had relieved the approved societies. The Government said to the societies: "You really do not require this extra money so much that we are justified in asking the taxpayer to find it for you." The societies had been able to distribute benefits among their members at a far higher level than they ever had any reason to expect, and when the whole country was suffering from a heavy burden of taxation it was not reasonable that they should go on accumulating surpluses at this rate. The actuary had given it as his considered opinion that the proposals of the Government would not touch any of the benefits which the societies had contracted to pay to their members. He thought that hon. Members opposite were too pessimistic about the future of the approved societies. They had seen a steady rise in the rate of accumulation of surpluses in the past. In the first period of six years they were £17,000,000; in the second period, which was only four years, there were accumulated surpluses including the carry forward and the contingency fund amounting to £15,000,000, and in the remaining period of only about two years it was already estimated that there were accumulated surpluses amounting to £20,000,000 additional. Under the Pensions Act the societies were relieved of the liability of cash benefit to people between 65 and 70, and that applied to additional benefits just as much as to normal benefits. The second point was that the average of contributions per year was steadily going up. At one time the average contribution was 43, but it was now 47. He dare say it would go higher still if unemployment continued to decrease. These were figures which gave them a certain amount of confidence in the future, and he was very strongly of the opinion that in spite of the diminution in the State contribution proposed in this Bill when the third valuation came round the surpluses would be sufficient to enable the approved societies to continue all the benefits which they had been able to declare under the second valuation.

### *Danger of Restricting Benefits.*

Dr. DRUMMOND SHIELS said that the more he considered *this measure the worse it seemed to get. He had hoped* that, as had been indicated by the right hon. gentleman on more than one occasion, the present benefits and the additional benefits which either had already been given or had been sanctioned under the second valuation would have been safe until 1931, but he thought it was very obvious on reconsideration of all the facts that even the extended benefits were in very great danger. He had been impressed with the ability displayed by the officials of the approved societies in the carrying out of their work, and he thought that their opinions were entitled to very serious consideration. There was no doubt they believed that not only would the further extension of medical benefit be prevented by this Bill, but where they paid the present extended benefit and gave extended medical treatment it would be impossible for them in many cases to carry on till 1931. The approved societies were faced with an immediate reduction of income starting from the time this Bill became law. There had not been very much said about the fact that the increased charge for medical benefit, which did not mean increased payment for the doctors, but was simply a transfer of the liability for the last increase from funds which the approved societies permitted to be raided two years ago, would undoubtedly involve an increased expenditure by approved societies. Therefore, as between the reduction of the State contribution and the increased cost of medical benefit it seemed to be quite inevitable that the splendid additional benefits which had been given by many societies would have either to be modified or withdrawn altogether, and certainly societies which did not give them now would not be able to give them in the future. Was this really economy? Take the matter of the dental benefit which had been given by a number of approved societies, but not by others. There could be no question about the tremendous value to public health of a dental service. Even from the point of view of economy it would be very desirable that a full dental service should be given by every approved society. It not only prevented many branches of disease, but it gave also a very greatly increased comfort and happiness to the individual. There was no question that this Bill when it became an Act would prevent the extension of this medical benefit in the shape in which it was already given, and in other cases it would prevent it being brought into operation. The same applied to optical benefit, which was of very great importance for those who required that form of treatment. Again, take the question of maternity benefit Various societies had been able to increase that benefit At the present time it only amounted to about £2, and all that money went either to the doctor or to the midwife and the person most concerned was left with the baby to hold. He thought it would be agreed that double the existing benefit, amounting to £4, which in some societies had been raised to £3 with the contributions of the husband and wife, if they were both insured, was about the least that was useful or desirable for maternity benefit It was extremely important that they should get to the stage of giving that benefit at as early a time as possible But that again was going to be prevented by this Bill. The Pensions Act was supposed to relieve approved societies of a liability of £37,000,000 He had not heard it stated that as against that provision had been made for a reduction of reserve value and prospective income of societies to an extent roughly equivalent to the amount of that relief. The circumstances which brought about the higher rate of interest had also increased in similar proportion the expenses of administration. One of the gravest charges against the Government in connexion with this matter was that they had gone against the recommendations of the Royal Commission, which contained among its members the Government Actuary, and which actually said that the payment by the Exchequer of its present proportionate share of the cost of benefits and their administration should be continued. The proposals of this Bill were not an economy at all, but a grave set-back to social progress. It was bad enough to diminish the prospect of continued extra benefit such as the dental, optical, and other benefits, but one of the worst things was the fact that the Bill postponed indefinitely the provision of specialist medical treatment Practically all the witnesses before the Royal Commission put those benefits first, and the Royal Commission put them first whenever funds were available. He did not think that hon. Members realised the tremendous importance which approved society officials and insured persons themselves attached to these services. At the present time if a well-to-do person was ill, and his doctor was in attendance on him, the doctor might come to the conclusion that a surgical operation was possibly required He might have some doubt as to the diagnosis, and he would then suggest to the relatives that he would like a second opinion. The relatives said, 'Certainly" Then the doctor could go to the telephone and call up a specialist, who came in an hour or two and the patient got the full benefit of the specialist service. In the case of an insured person the man s doctor might be in the same difficulty If he put the same question to the relatives they would say that they could not afford a specialist s fee. Then the doctor would have to say: 'We will have to try the hospital.' But, as he had pointed out in the debate in the second reading of this Bill, so far as Scotland was concerned —and he thought that the same applied to England—there was a waiting list in the six main Scottish hospitals of 5800 people waiting for beds. The Committee which had just been considering the question of the Scottish hospitals had reported that many of these people suffered as a result of their waiting and some even died, as a result of hanging on waiting for a bed. He felt that the insurance medical service would never be anything but partial and very unsatisfactory until it included the fullest possible benefits which modern medical science could give. A new arrangement with the doctors was imminent, and would take place at the end of this year, but supposing that a composite arrangement might be made would it include a specialist service? The additional medical charge in view of the financial circumstances of the approved societies would make the position of the societies impossible. He was afraid, therefore, that the specialist inclusive service they might have had normally next year must be put off now until some unknown time. Many approved societies had realised the importance of these specialist services and had made arrangements with hospitals nursing associations, dispensaries, and other organisations, in order that a certain amount of specialist service and institutional treatment might be secured for their members. That would probably be cut off at once, because it was paid for not out of the surplus but out of the ordinary benefit fund. So it seemed to him that the hospital problem, which was deplorably bad in Scotland and also in England, would be made worse as a result of the cutting off of these contributions. If there was any money to spare in connexion with this fund there were innumerable ways in which it could be spent, not only for the advantage of the insured people, but also to make the fund what it was proposed to be at first—a full and complete medical service for the very humblest insurance contributors.

The closure having been carried, Mr Thomas s amendment was negatived by 209 votes to 118

Mr BLUNDELL moved an amendment providing that the Government should continue to pay their two-ninths contribution towards the cost of the statutory benefits, and that the societies should bear the cost of the other benefits which they were able to provide That would mean that the Government would save a considerable sum of money without upsetting the finances of the approved societies. They would save, according to the actuaries' report, £1,200,000 in 1926-27, £1,500,000 in the following year, and thereafter an average of £1,200,000

Mr CHAMBERLAIN said the amendment was a very startling one It meant that from the financial point of view he was going to lose, if he accepted the amendment, £1,500,000 in the first year out of the £2,800,000 and £1 000,000 a year after that. He was not closing his mind to any modification in the Bill which did not go to the root of its vital principles. But to cut the saving in half was obviously more than he could be expected to accept If the hon. gentleman could suggest some way of covering the proposal which would go some way towards meeting his fears, and at the same time would not cut away the savings until they were no longer perceptible, he should be glad to discuss matters with him.

Mr BLUNDELL expressed his willingness to withdraw the amendment but the Opposition objected The closure was carried by 200 votes to 114, and the amendment was then rejected without a division.

Progress was reported

## Medical News.

UNIVERSITY OF LONDON.—Amongst the recipients of degrees on March 24th were Margaret M. A. Murray (M.Sc., physiology), Egon Sharpe Pearson (D.Sc., statistics), and Ethel May Newbold and Leonard H C. Tippett (M.Sc., statistics)

The following have satisfied the examiners in Part I of the Third Examination in Dental Surgery: Cyril Hall, Frank S. Kursin, and Cyril G Walmsley, all of Guy's Hospital.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND —At recent examinations for the Diploma in Tropical Medicine and Hygiene the following candidates were successful —

Ahmed Khalil Abdel Khalik and Mahmoud Abdel Hamid Atiya, Cairo, Basil N V Bailey, Edinburgh, Hargobind Lal Batra Punjab and Edinburgh, Hugh B Boucher, St. Thomas's, Gwendolen S M. Chataway, Royal Free and St. Mary's Ernest E. Claxton, St Bart.'s; Abdel Kader Hilmi El Shurbagi, Cairo, Silvio C Gomes, Edinburgh; Geoffrey D Gordon Cambridge and St. Thomas's, Frank G Greenwood, St. Bart.'s, John R. Hayman, Middlesex and Royal Army Medical College, Margaret Holliday, Dublin, Laura M Jacobs, Royal Free and St. Mary's, John J Keevil Cambridge and St. Thomas's, Harold D B. Miller, Melbourne; Richard M. Morris, Cape and London, Edward A Penny, Guy's John O. Pyper, Glasgow, Reginald D Reid St. Bart.'s, Ernest A. Struthers, St. Andrews, Arthur G Taylor, Birmingham Leo G W Urich, Middlesex; William J Webster, Aberdeen, Isabel J Woodhouse, Royal Free, Li Tsoo Yiu, Hong Kong, and William A. Young, Oxford and St. Thomas's. (All the above with one exception were students at the London School of Hygiene and Tropical Medicine)

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following candidates were successful:—

### FINAL MEDICAL EXAMINATION

*Part I., Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene, Pathology and Bacteriology*—*Robert R. Woods, *Maurice F N Griffin *Thomas C. M. Corbet, Maximilian Gerber Edward G Montgomery, Isidore Isaacson, Samuel R. Elmes, Ralph W T H. Stewart, Hyman Dundon, Henry A. Ferguson, John M M Elligott, Louis R. Brumberg Isaac F Ratthaus, Wilhelm F Knobel John K Harper, and Cecil F Cope.

*Part II, Medicine*—*Henry O Clarke, *Arthur J Conlin, Ernest H Hall, Philip F. Palmer, George A. Walmsley, Thomas J W. Keown, William O. G Potts, Jack M. Selkon, Edward W Bingham Malben A. W Roberts, Nancie N Lowther Andrew L. A. O Byrne, Isabella K. M Neilly, Elias Rakoff, Kathleen I Purdy, Thomas F M Woods, Samuel Smyth George W H Townsend, Richard T P Tweedy, Gerald V A. Griffith George G M Farland, Donald B. O'Sullivan Beare, Edward H Harte Evelyn E. Connolly, Caleb P Wallace James Craig, James G. M Dowell, Robert H Mitchell, Ernest E. Malone, and Daniel J Roux.

*Surgery*—*Seymour F Heatley, Ransome M Allardyce, George W H Townsend Charles R. Boland, George A. Miller Henry J Roche David N Power, John H M Lean, Margaret W Pike, Mary S Miller, Richard G Keays, Johan N S. Gouws, Joseph V Pincus William Russell, Herbert Nelson, Gerald A. A. Powell, Lucy E. R. Pigott, Mabel E. Brittain, Cicero G. Nel, Gilbert T. L. Archer, Arthur B. Brooks, Wolsey C. Sloan, James F. MacMahon, William G. Maule, Albert Sachs, Charles L. Taylor, and William Magowan.

*Midwifery.*—*Ernest E. Malone, Ernest E. Satchwell, Samuel Smyth, Derek St. C. Mackenzie, Henry A. Ferguson, John Quigley, John B. Patrick, Charles F. M. Wilson, Martinus G. J. Booysen, Norah E. Fenton, John Johnston, Norman J. U. Mather, and William P. Culbertson.

* Passed on high marks.

INTERMEDIATE DENTAL EXAMINATION.

*Anatomy and Physiology.*—Francis J. P. M'Carthy.

FINAL DENTAL EXAMINATION.

*Dental Surgery and Pathology; Dental Mechanics and Metallurgy; Orthodontics.*—Eric N. Guise-Brown.

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS.

Isaac Valvl Yoffa.

AUXILIARY ROYAL ARMY MEDICAL CORPS.—The annual meeting of the members of the Auxiliary Royal Army Medical Corps Funds will be held at 2.30 P.M. on Friday, April 23rd, at 11, Chandos-street, Cavendish-square, London, W., when the annual report and financial statement for 1925 will be presented, and the officers and committee for the current year will be elected.

JOINT TUBERCULOSIS COUNCIL: POST-GRADUATE COURSES ON TUBERCULOSIS.—As already announced (THE LANCET, Feb. 20th, p. 403), Prof. S. Lyle Cummins will hold an intensive course at Cardiff from April 12th to 17th for medical men and women specially engaged in tuberculosis work. There will also be a similar course in London from April 19th to 24th. Inquiries should be addressed to the hon. secretary at 19, Brunswick-square, London, S.E. 5.

HUNTERIAN SOCIETY.—The Council of this Society has presented a satisfactory report for the session 1925-26, so that it has been possible to consider the question of resuming the publication of the Proceedings in volume form. As, however, this means the institution of a guarantee fund, the Council will invite expressions of opinion from the constituency. The report also places before the Fellows the advisability of appointing a librarian, in view of the fact that an important collection of books belonging to the Society has been for many years in private keeping. Mr. A. E. Mortimer Woolf has been nominated as President on the retirement of Dr. Howard Humphris.—A dinner meeting of the Society will be held at Simpson's Restaurant, Cheapside, London, on Monday, April 12th, at 7.30 P.M. At 8.30 P.M. the annual general meeting will begin, after which Lord Hewart (the Lord Chief Justice) will read a paper on Criminal Law and its Relation to Insanity.

POST-GRADUATE VACATION COURSE AT DAVOS.—A course dealing generally with tuberculosis and alpine climate (the third of its kind) will be held in Davos from August 22nd to 27th. The programme will include lectures and demonstrations by the medical men of Davos, on the climatology, pathology, diagnosis, and prognosis of tuberculosis. The lectures are given chiefly in French and German, but arrangements are being made this year for certain lectures and demonstrations to be given in English. It is hoped that many English medical men will avail themselves of this opportunity of seeing the great tuberculosis centre of Davos. In former years the course has been largely attended by continental medical men and students, but so far the English attendance has been very meagre. Dr. Bernard Hudson, of the Victoria Sanatorium, Davos-Platz, Grisons, Switzerland, would be glad to supply any further information or assistance, and full particulars will be published later. There will be special terms for railway travel and hotel accommodation.

THE LATE DR. G. W. MALIM.—Dr. George Warcup Malim, who died on March 31st at the age of 80, came of a Lincolnshire family which for generations had given a son to the church, law, and medicine. Educated at Grantham Grammar School, he received his medical training at Birmingham and Guy's Hospital, qualifying as M.R.C.S. and L.S.A. in 1865. After some experience in Bilston in Staffordshire and elsewhere, he went to Rochdale 55 years ago, and there built up a large practice from which he retired only two and a half years ago. Dr. Malim was an out-and-out opponent of the Health Insurance Acts, and resolutely refused to join the panel. He was appointed a justice of the peace for the borough of Rochdale in 1885, and at the time of his retirement was the oldest resident magistrate as well as the oldest medical practitioner in the town. A man of warm and generous sympathies, he won the confidence and affection of his patients, and when he retired was followed by the gratitude and good wishes of his many friends. Of the family of 12, of which Dr. Malim was a member, six are still living. His wife died many years ago; he leaves three daughters.

SIR KINGSLEY WOOD, Parliamentary Secretary, Ministry of Health, has appointed Capt. D. W. Gunston, *M.C.*, M.P., to be his Parliamentary Private Secretary (unpaid).

THE Home Secretary has appointed Lieut.-Colonel John Allan Anderson (formerly of the Royal Army Medical College) to be an Inspector under the Cruelty to Animals Act, 1876.

THE death is announced from Melbourne, Australia, at the age of 71, of Sir Harry Brookes Allen, Dean of the Faculty of Medicine and for many years professor of pathology in the University of Melbourne.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society will be held at the Miller General Hospital, Greenwich, to-day, Friday, April 9th, at 8.45 P.M., when Dr. E. P. Cumberbatch will read a paper on the Treatment of Gonococcal Infections by Diathermy.

SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL.—Colonel R. J. Blackham, M.D., will take the chair at a debate on Birth Control to be held at the Essex Hall, Essex-street, Strand, London, on April 22nd, at 8.15 P.M. Lord Morris will represent the Roman Catholic point of view and Dr. Marie Stopes will speak for the society.

NO. 55 GENERAL HOSPITAL B.E.F.—A reunion dinner will be held at the Trocadero Restaurant, Shaftesbury-avenue, on Saturday, May 15th, at 7 for 7.15 P.M. Old officers intending to be present are asked to communicate at once with Dr. H. B. Roderick, 17, Trumpington-street, Cambridge.

MEDICO-LEGAL SOCIETY.—At an ordinary meeting of this society to be held on Tuesday, April 20th, at 11, Chandos-street, Cavendish square, London, W., at 8.30 P.M., Mr. C. Ainsworth Mitchell will read a paper on Some Aspects of the New Regulations on Preservatives. At the discussion following members of the Society may introduce guests.

LONDON FEVER HOSPITAL.—The 104th annual report shows that the fever patients treated were fewer by 103 than in 1924, in consequence of a fall in the number of cases of measles. But while there were only 39 patients suffering from measles, as against 249 in the preceding year, 196 cases of rubella were admitted—almost as many as the total of the previous four years. There were no deaths from measles or enteric (of which there were only six cases): there was one death from scarlet fever and one from diphtheria. Among the nursing and domestic staff there were 13 cases of diphtheria, three of scarlet fever, and one of rubella.

"CRITICAL CONDITION" OF THE LIVERPOOL HOSPITALS.—Mr. H. Wade Deacon, the chairman, at the annual meeting of the committee of the Liverpool Royal Infirmary, declared that as regards the large general hospitals in the city the voluntary system is in a critical condition. The four large hospitals are getting ever more deeply into debt, but they have agreed not to issue any appeals until the Lord Mayor's Committee has matured its plans for the establishment of a contributory scheme. Mr. Wade Deacon, who has been chairman of the Royal Infirmary since 1912, and has also been chairman of the British Hospitals Association, was last week publicly presented with his portrait by the Lord Mayor of Liverpool in recognition of his services.

THE LATE DR. J. BROWNLEE MILNE.—Dr. John Brownlee Milne, of Penmachno, Bettws-y-Coed, died suddenly at Llandudno railway station on March 16th; he had suffered from heart trouble for many years. Dr. Milne was 46 years of age and a native of Montrose. He graduated M.B. and Ch.B. at the University of Edinburgh in 1900 and then was house surgeon in the Bradford Children's Hospital and in the Stanley Hospital, Liverpool. He practised for a time in Hull and also in the London district; after the war he went back to Liverpool as a ship's surgeon. He served in the war as a captain in the R.A.M.C. and was badly wounded at Arras. At the time of his death he held the appointment of medical officer for Penmachno and public vaccinator for Llanrwst and district.

THE OPTICAL CONVENTION.—Mr. Stanley Baldwin, the Prime Minister, will open the Convention (of which an account appeared in THE LANCET, Feb. 27th, p. 452) on Monday, April 12th, at noon, at the Imperial College of Science, South Kensington. The Convention will last until April 17th and meets under the presidency of Sir Frank Dyson, the Astronomer Royal. It is intended that every branch of science and industry which is interested in optics shall be represented, and the papers and exhibition cover a correspondingly wide range of subjects. For the less erudite there will be popular lectures and an entertainment section which bids fair to be very entertaining indeed. The offices of the Convention are at 1, Lowther-gardens, Exhibition-road, London, S.W.

Sir James Barr has been elected President of the Royal Infirmary, Liverpool

Nottingham Hospital Saturday Fund —Last year the collections for this fund reached £28,708, the largest total yet obtained. This sum supplies more than half the financial needs of the Nottingham General Hospital

Presentation to a Medical Man —Mr J Ernest Nevins, M.B Lond, M R C S Eng, has been presented by the staff at Brownlow hill Infirmary, Liverpool, with a Chippendale cabinet with some other gifts, on his retirement from the post of visiting physician to the infirmary after 26 years service.

The late Dr. R B Alston —In the course of an examination at St. Thomas's Hospital on March 18th for a medal in pathology Dr Ronald Bruce Alston pricked his finger whilst making a post-mortem examination and died from septicæmia ten days later A day or two after the accident he had complained of pain and swelling in the finger, but said that he did not remember having injured it Dr Alston was a student at St. Thomas's Hospital, and qualified M R.C.S., L.R.C.P in October, 1925

"Records" at Coventry —The annual report of the Coventry and Warwickshire Hospital shows not only a record income—over £10,000—but that the number of patients was greater than ever before. The pressure upon the X ray, electrical, and massage departments was so great that it was found necessary to increase the staff and instal more apparatus. It is hoped that by the end of the present year the money needed for extensions will be forthcoming The report says that a second operating theatre is an imperative necessity The hospital, which contains 241 beds, a number that is now totally inadequate, has been five times enlarged in less than 20 years.

St Andrew's Hospital, Dollis Hill.—The annual report of this Roman Catholic foundation of 52 beds states that whereas in 1913, the year in which it was opened, 540 patients were received, in 1925 the number reached 900 By affiliation with the Royal Free Hospital it is now recognised as a training school for nurses, more accommodation for whom is urgently needed. The hospital is intended for patients who, while not suitable subjects for free reception in charitable institutions, are yet unable to meet the cost of adequate medical or surgical treatment in private nursing homes. Patients are admitted only on the recommendation of their own medical adviser, and in a certain number of beds preference is given to patients of French-speaking countries.

Dr. Jessie Macgregor Prize.—This prize of 60 guineas will be awarded in July next to the woman graduate or qualified woman student of the University of Edinburgh who presents the best record of original work in the science of medicine. Such work may be published *or unpublished but must not have been* published earlier than July 1923. The successful applicant shall within six months following the award, deliver a lecture to the medical profession in Edinburgh on the subject of the work for which the prize has been awarded. Applications marked Dr Jessie Macgregor Prize in Medical Science' must reach the Convener of Trustees, Royal College of Physicians of Edinburgh, not later than June 30th.

The late Dr J B Yelf —Dr John Burnet Yelf, who died at Hemel Hempstead on Feb 28th, was born in 1871 and was the son of the late Dr L. K. Yelf of Moreton in-the-Marsh. He was educated at Epsom and went on to St Mary's Hospital, qualifying M R.C.S and L.R.C.P at the age of 22 After house appointments there Dr Yelf settled at Shipston-on-Stour in Worcestershire where he remained in practice until last year, when failing health enforced his retirement He served in the Royal Army Medical Corps during the war He took a great interest in sport and in local affairs generally, and was also a keen Freemason; his death will be deeply regretted in the district In 1891 Dr Yelf married the daughter of Mr John Barnard of Gloucester, by whom he had one son and two daughters.

Welfare of Edinburgh Children —The report of the Edinburgh public health department for the past month contains a comparison of the condition of children under 5 years of age in 1913-14 and 1923-24 Dirty clothing is less common in the later period; a verminous state of the head is *more frequent among* boys but less frequent among girls—presumably because of shorter hair; really bad nutrition is distinctly rare; the condition of the teeth appears to be worse Heights and weights show little change. Enlargement of lymphatic glands seems less common (perhaps, it is suggested, because the milk-supply has improved); the percentage of children described as having squint has increased; and the number *of vaccinated* children is smaller

Maternity Work at Bristol.—At the annual meeting of Bristol Royal Infirmary it was stated that in consequence of the city's unsatisfactory housing accommodation one out of every six children born in Bristol is dealt with by the hospital, within or without its walls. The *ordinary expenditure last year exceeded the ordinary* income by £8000

The late Mr C E. Pronger.—Mr Charles Ernest Pronger, who died on April 2nd at his home in Harrogate, studied medicine at St Thomas's Hospital, becoming L.R.C.P Lond in 1876 and F R.C.S. Eng in 1891 He was assistant demonstrator of anatomy at St. Thomas's Hospital. For a time he was in general practice in Barnstaple and was attached as surgeon to the Barnstaple and North Devon Infirmary, later becoming consulting surgeon to that institution He settled in Harrogate in 1892 as an ophthalmic surgeon and soon developed a wide consulting practice. For many years he was attached to the Harrogate Infirmary, where he started the eye department, raising the money for its establishment, and he was also ophthalmic surgeon to the Yorkshire Home for Incurables and to the Northern Police Orphanage He made a special study of refractive errors and was one of the first to emphasise the importance of correcting the minor degrees, pointing out that the grosser errors do not cause so much upset to the individual as the lesser ones which produce a constant strain. Mr Pronger did all he could to promulgate this view by monographs and contributions to medical journals and could show excellent results in his own practice. He was an enthusiast in his special work and followed up his cases afterwards. For recreation he was a keen golfer and was at one time captain of the Harrogate Golf Club He leaves a widow, but no family.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Petworth (Sussex), Swanage (Dorset), and at Upton (Worcester).

# Births, Marriages, and Deaths.

## BIRTHS.

Bates.—On March 30th, at Welbeck-street, the wife of Dr. Kenneth Bates, of St. Albans, of a daughter.

Foley.—On March 30th, at Ebury-street, S.W., the wife of Walter Foley, F.R.C.S., of a daughter.

Wilson.—At Jhelum, India, on March 7th, to Dagmar Curjel Wilson, M.D. Glasg., D.P.H. Camb., wife of W. R. Wilson, Indian Civil Service, a son.

## MARRIAGES.

Stockton—Rowntree.—On March 31st, at the Friends' Meeting House, Hampstead, Edward Latham Stockton, to Alysoun Hurndall Rowntree, M.R.C.S., L.R.C.P.

## DEATHS.

Alston.—On March 28th, at St. Thomas's Hospital, of septicæmia, Ronald Bruce Alston, M.R.C.S., L.R.C.P., aged 22.

Bigg.—On Easter Day, at Morpeth-mansions, S.W., George Sherman Bigg, F.R.C.S. Edin. (late Capt.-Surgeon, R.A.M.C.).

Haworth.—On March 13th, at Salisbury, Rhodesia, as the result of an accident, Wallace E. Haworth, M.B., C.M., B.Sc., Entomologist to the Administration of Southern Rhodesia at Salisbury.

McLuskie.—On Palm Sunday, following an operation, Peter McLuskie, M.B., Ch.B., D.P.M., aged 33 years.

Pronger.—On Good Friday, at Litchdon, Harrogate, Charles Ernest Pronger, F.R.C.S. Eng.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Comments, and Abstracts.

## SOME CURIOSITIES OF CLINICAL MEDICINE.

By C. E. Shelly, M.D. Camb., M.R.C.P. Lond.

### I.

Everyone in the course of medical practice has had experiences where the development of a case or the application of a treatment has had what I may call its curious side. Either some apparently unrelated circumstances fall into the picture or some therapeutic measure has an unusually valuable result, and such experiences are made more useful if it is possible to show that we have in them illustrations of cause and effect along scientific lines. Explanations of the phenomena, as they turn up in the course of practice, are not always possible at the time, but I feel that records should be made because a solution of what was puzzling may afterwards result from observation of similar happenings, while, if they are published, others, with the facts before them, may be able to supply the reasons. "Given a fact, find the explanation of it. But, is it a fact?" said Lauder Brunton.

The word "curiosity" is used in this connexion—not in its more modern sense of something rare, strange, even bizarre, but with more conformity to its original meaning, as indicating some deviation from the normal which arrests attention, calls for "careful" investigation, and demands, if possible, a satisfactory explanation.

### Post-Influenzal Diabetes.

I suppose that few of us, after a patient has apparently completely recovered from an attack of influenza, continue to go on testing his urine.

Some 20 years since a lady who had suffered, not severely, from an attack of influenza rather more than three months previously, sought advice on account of feeling "weak and run down," as she expressed it. Examination showed, inter alia, a urine of high specific gravity, containing an appreciable amount of sugar. She did not complain of thirst, although admitting that she was rather more thirsty than usual—attributing this to the hot weather. There did not appear to be any obvious cause for the glycosuria; but I remembered that the particular epidemic of influenza in which she was a sufferer was generally characterised by rather marked gastro-intestinal symptoms. Neither she nor any of the other cases had, however, developed any trace of glycosuria during the illness, nor during the period of what appeared to be a complete convalescence.

But I made occasion for examining a specimen of the day's urine now being passed by each of the influenza patients who had then passed through my hands. Sugar, in varying amount, was found in nine cases. Five of these were cured, and have remained well ever since. Two—an old gentleman and an old lady, both in feeble health—died within three and nine months respectively. Of the remaining two—who had left the neighbourhood in apparently good health—one died within a year, and the other, after some temporary improvement at the beginning of the third year, of true *diabetes mellitus.*

The inference would seem to be that influenza, especially if of the "gastro-intestinal" type, is apt to be followed by the development of diabetes, although this may not declare itself for several weeks after an apparently complete recovery of the initial malady; and that a full examination of the urine is called for in every such case at intervals, for some weeks at least after all influenzal symptoms have subsided, however well the patient may then seem to be. I have found sugar in the urine of five such patients thus examined; all made a good recovery.

There is, of course, nothing surprising in the pancreas becoming functionally affected in the course of a gastro-intestinal inflammation; either directly owing to its invasion by the specific organism or by the extension of an inflammatory process from the duodenum viâ the pancreatic duct. In none of the fatal cases mentioned was a post-mortem examination obtained.

### Chloroform and the Diphtheria Carrier.

There are few cases more exasperating to all concerned than that provided by the diphtheria carrier.

An instance of this came under my care some years ago. A schoolboy of about 13, who had made a good recovery from a mild attack of diphtheria, and who appeared to be in buoyant good health, but whose swabs from the right nostril continued regularly to furnish evidence of a local, virulent, and persistent culture of K.L. bacilli. No treatment had proved of any service. Schoolmasters, parents, and doctors were all naturally and seriously chagrined;

and the lad himself had long become weary of his enforced ostracism. Fortunately for him it was summer-time and bright summer weather.

One viewed the details of the local infection as representing an inaccessible rocky fastness to which a band of practised marauders had retreated with their flocks and herds, and in which they seemed able to maintain themselves in comfort indefinitely. Their natural fortress was encircled by a zone of gendarmes (active leucocytes), who could make no direct attack and whose activity was limited to maintaining an ineffective siege. For the space between the two opposing forces was a sort of no-man's-land, which none could attempt to cross without certain death. The only method of destroying the marauders seemed to be by the discharge of poison-gas bombs from aeroplanes or airships flying above them.

About this time the value of small doses of chloroform per os as an effective treatment of the typhoid carrier was being vaunted; and it struck me that this might prove no less serviceable in relation to the diphtheria bacillus. I was the more encouraged in this view by recalling the relative action of ether and of chloroform upon much higher forms of vegetable life. If ethyl ether be injected beneath the bark, into the cambium layer, of a fruit tree, for example, the result is a stimulating one; efflorescence is earlier and more profuse, fruit and foliage are more abundant—the whole life of the tree is activated. But if chloroform be used in the same way the result is, as it were, to send the tree to sleep—blossom appears late, small in amount and feeble in vitality; fruitage is poor, alike in amount, size, and quality; the whole tree is enfeebled.

One might reasonably imagine that, in the course of its evolution, the diphtheria bacillus would have had no opportunity of developing a special immunity to chloroform. It was possible that the guardian leucocytes might at the same time be relatively enfeebled, perhaps even destroyed, by the anæsthetic. But this would be of no importance, if only the virulent bacilli were simultaneously extirpated. In any case, the experiment seemed worth a trial and it could do no harm.

The patient had for some weeks previously been using an alkaline disinfectant spray and douche for nose and throat three or four times daily. This was ordered to be continued as before, save that it was to be made up with chloroform water as the excipient in place of distilled water. At the end of five days all local treatment was discontinued for 48 hours, and swabs were then taken from nose and throat. They were reported to contain no K.L.B. or similar organism. At the end of a second and of a third week, the report was the same. After a resumption of the treatment for three days no treatment was given for a week; swabs taken at the end of that period were also negative. No further treatment was given for yet another week; and then, as the report was again negative, the lad was restored to his normal position in society, without anyone being the worse.

I have since had opportunities of treating a few similar cases with equally happy results. And, though such a record can hardly be claimed as settling the matter for good and all, it would seem to justify the use of such treatment in any similar case; and, also, I venture to think, the use of like measures from the beginning of every case of diphtheria, whether its nature be established or only suspected.

How the chloroform acts, whether, like mercuric chloride, it combines with the chitinous envelope of the microbe and so stiffens this as to render any change of form impossible, or whether it asphyxiates the aerobic organism outright, I do not know. In either case, a bacterium which is made absolutely immobile can neither feed nor subdivide, and therefore such a bacterium can neither grow nor propagate its race; it dies—which is the result at which we aim.

### A UNIQUE CASE OF REVACCINATION.

On a certain Tuesday more than 20 years ago a Miss C. wrote to me asking to be revaccinated on the following Thursday. She was at that time running a small crêche in the East End of London and spent several days of each week in actively superintending its management. A small epidemic of small-pox had recently broken out in the neighbourhood and she explained that her mother was extremely anxious that she should be revaccinated.

The daughter regarded this as quite unnecessary; she had undergone revaccination five years previously, without its "taking." She herself was assured that she was still immune, and she very much resented having to keep one of her arms in a sling, debarred from active use, even if only for the three or four days which might be requisite before it could be ascertained whether the revaccination were successful or not. Still, in deference to her mother's entreaties, she had, most reluctantly, consented. She was vaccinated on the Thursday morning with fresh lymph of proved efficiency and was told that a revaccination often followed a course less regular than that of a primary vaccination, and that the usual signs of a reaction might be relatively delayed. She was seen on the morning of the fourth day, when there was not the faintest sign of reaction; and at the end of the full week she wrote to me saying that her arm was still quite free from the slightest irritation of any kind. We therefore concluded that the immunity conferred by earlier vaccinations was probably fully maintained, and she resumed her visits to town.

About a week later she wrote again; the local epidemic was spreading; her mother was still dissatisfied, urging that the operation should be repeated; and the daughter had again acceded to the mother's continued pleadings. Of course, it was all nonsense, she wrote, and quite unnecessary; while admitting that at times she was almost prompted to wish that the second attempt might prove successful, and the whole business be got over for good and all—even at the price of having to put the arm out of commission for ten days or a fortnight. This second attempt was fixed for the morning of what was the sixteenth day after the first.

I found the mother sitting at a work-table, engaged on some embroidery, the daughter standing beside her. All that I needed in the way of hot water, clean towels, and soap, were ready at hand. I asked the daughter to remove her bodice, and while she was doing so made the necessary preparations. As I was about to break off the end of a tube of lymph I stopped; then I looked at Miss C. and caught her glance; then I looked at her bared arm again without speaking. She looked at her arm, turned slightly, so as to hide that shoulder from her mother, and said quietly: "Mother, do you remember my coming into your room this morning?" "Yes," was the reply. "You came into my room after your bath and finished your dressing there. Why do you ask?" "Do you remember what you said to me while I was dressing?" asked Miss C. "Yes. I looked at your arm and said, 'Well, you've got nothing there to show your doctor this morning when he comes.'" "Well then, look now," turning so that her mother could obtain a full view of the left arm and shoulder. The site of the vaccination performed a full sixteen days previously was now occupied by a pustule more than half an inch square (two of the three scarifications had coalesced), presenting an appearance in accordance with the date, a fully-formed pustule, beginning to darken and crust around its margins. Its further development, with ultimate separation of the dried-up pustule from the usual foveate scar, was quite normal.

The only explanation of this unusual sequence of events, the prolonged stage of non-reaction, followed by the sudden appearance of a full-blown pustule, which must have visually developed within not less than three and a half hours at the most, and possibly within a much shorter time, is that furnished by self-suggestion. Miss C. was a very capable, accomplished, and level-headed young woman of about 35, descended from a hard-headed Yorkshire stock, possessing great determination, and without a trace of hysteria or other nervous weakness in her individuality. In the first instance she was most strongly opposed to the suggested vaccination; it was, she thought, unnecessary and certain to be unsuccessful; if it were performed without its "taking" she would be the sooner free to resume the work in which she was so deeply interested; therefore it should not occur. This her subliminal consciousness accepted as a mandate that it must not occur, at least, must not "take"—i.e., give any visible sign of its having taken. And here we perceive an action similar to that of blushing, which reddens such portions of the skin as are visible to others. In this case it was the outward and visible sign of the vaccination's having "taken" that was chiefly in the mind of the patient, since it was on the presence or absence of such obvious evidence that the limitation or the freedom of movement allowed to the limb would actually depend. Therefore, no local evidence made its appearance: it was indefinitely deferred. But as soon as she again changed her mind, in deference to her mother's wishes for a second revaccination, the position became reversed. Her mental attitude was now somewhat like this: "Oh, for heaven's sake, let me have this revaccination done and let it take, if possible, so that the matter may be settled once for all and there may be no excuse for its repetition." Whereupon, the subconscious ban was not only removed, but all her mental energy, both conscious and subconscious, was directed towards achieving a speedy and complete visible evidence of effective inoculation.

There is at least some reason for assuming that the time of the appearance of this external evidence of successful vaccination coincided very closely with that of my inspection of the arm. For one thing, it is unlikely that it could have made its appearance much earlier without attracting the patient's own attention to the part, as by some unusual local irritation caused by friction of the clothing, or the like. And we have abundant evidence founded on numerous instances in which most serious inflammatory lesions of the surface of the body, even actual gangrene of the part, have instantaneously developed in individuals who had been "shocked" by suddenly seeing similar lesions, affecting the same part of the body, in another.

Further consideration of this case suggests some interesting problems :—

1. Was the patient in any degree protected against variola during the period for which the superficial evidence of a successful vaccination was lacking? This can hardly be answered off-hand one way or the other. In the first place we know that the vaccinial fluid is not absorbed by the sound, unbroken skin. No one, so far as I know, has succeeded in producing a vaccine vesicle by rubbing the vaccine of cow-pox into the sound, healthy skin. To effect this the superficial (dead) cells of the epidermal layer must first either be removed by friction, or cut or scratched through, so that the active vaccine may be absorbed by the living cells of the corium beneath; such cells exist in the corium and also, to a relatively small extent, in the deepest layer of the true epidermis.

Now, in Miss C.'s case, the corium was reached at the first revaccination; there was bleeding, though very slight, from each of the three scarifications; and there is evidence that the vaccine subsequently rubbed in was absorbed by it. The slight scarification wounds speedily closed and healed—i.e., the area of inoculated corium became covered by a thin layer of apparently unbroken epithelium, as happens in the case of any ordinary, unpoisoned superficial scratch—hiding from view the activities or potential activities imprisoned beneath that small area. Further, we know that in the course of the following 15 or 16 days the small patch of infected ("vaccinated") corium passed through the usual developments, resulting in its being revealed at the end of that time as a well-developed vaccine pustule bearing an appearance corresponding to its age.

But why did not this pustule show up on the surface of the skin before this date? This delay, I think we must agree, was due to the restraining influence of the "subliminal ban." And I incline to think the ban acted by way of a powerful stimulation upon the energies of the protective phagocytes present in the most superficial layer of the corium and in the deeper part of the epithelium, into which it imperceptibly merges. We must remember that what the patient's mind was now concerned with was the ocular evidence—the outward and visible sign—of a successful vaccination; at the beginning she had laid a ban upon the production of such evidence; whereupon there was "whipped up," as it were, a powerful array of white blood-cells whose number and energy did suffice to prevent the virus finding its way to the surface of the skin. Later on this ban was removed and, with its removal, the local force of defensive leucocytes was disbanded, and there then remained no obstacle to the evidence of vaccinial suppuration promptly reaching the surface.

It is only reasonable to suppose that meanwhile, beginning almost immediately after the performance of the vaccination, the vaccinial virus had been actively modifying the vital qualities of the living tissues in its neighbourhood; the results of such action would be carried throughout the body by blood and lymph streams producing the usual effects. And one can discover no good reason why this action should be any the less effective in immunising the patient against variola, simply because the mere superficial tokens of its activity happen to have been temporarily delayed.

2. What would have occurred if the mother had not pleaded for a second revaccination, and if both she and her daughter had been content with the, apparently, ineffective first revaccination? The patient would have been content with this issue of events. She would cease to worry any more about the subject. Her thoughts, once more diverted into their ordinary channels, would no longer be keeping the subconscious self up to its work; it would consequently relax its efforts, and sooner or later would abandon them altogether. Thus the ban would be removed and the external ocular evidence of successful vaccination, a ripe, matured pustule, would suddenly make its appearance. If this occurred during a dance or a dinner party it would have been a portent as disquieting, not to say alarming, as it would be incomprehensible to the spectators and to the victim. But if this removal or extinction of the ban did not occur until some full three weeks or more after the date of vaccination we should not expect any cutaneous sign. Such a period would cover the whole time required for the full development, maturation, and disappearance of the vaccine pustule, and its last disintegrated remnants would have been removed subcutaneously. The patient would have been noted as "unsuccessfully revaccinated."

I was able, soon after the events just narrated, to carry out some experiments on the psychological aspect of vaccination. Adolescence is a period of rapid metabolism. The public schoolboy on his entrance, at about 13 years of age, is almost invariably susceptible to revaccination, and at the termination of his school career the percentage of successful revaccinations is not less than 98 to 99. Seventeen of such lads presented themselves for revaccination under the Army entrance regulations. Their ages varied from 17 to 18·5 years. They were divided into three groups: A, numbering 5; B, numbering 5; and C, numbering 7. Each group was vaccinated separately. Those in Group A were told that some evidence of the lymph having "taken" would be visible by the second or third day. B were told that such evidence would not appear before the evening of the fifth or on the sixth day. To Group C nothing was said. The same stock of lymph was used for all.

In the members of Group A reaction occurred on the evening of the second day in two cases; during the night or early morning, in three cases. In Group B the results were: evening of the fifth day, two; during the same night, two; morning of sixth day, one. In Group C the first evidence appeared: by evening of third day, one; during the following night, one; on the fourth and fifth days, three and two respectively. On two subsequent occasions, with a total of 11 and 9 respectively, who were separately told to expect results on the second and on the fifth day, the discrepancy was rather more marked. In the larger group (of 11) there was one complete failure—he had been revaccinated two years previously.

The late Sir George Paget believed that every convalescent from typhoid fever was fully susceptible to revaccination, even though he might have undergone a successful vaccination just before his attack of typhoid. I do not know whether other observers have made similar investigations. But the point might be worth bearing in mind in relation to every patient recovering from typhoid.

The sudden eruption of the fully-formed vaccinia pustule, as recorded in the case of Miss C., recalls the story of Gehazi. It would not be unreasonable, and it would not involve less of a "miracle," to imagine that Gehazi might have already contracted leprosy during his service with his master, Elisha, although any definite outward manifestations of the disease had not as yet become apparent; and that, stricken with sudden terror and remorse by the prophet's malediction, completely unmanned and acutely visualising his appalling doom, the external evidences of the malady immediately developed, so that he fled from Elisha's presence "a leper as white as snow."

(*To be continued.*)

## THE SCANDAL OF THE SCALES.

*To the Editor of* The Lancet.

Sir,—A convalescent was recently weighed on four scales in different chemists' shops in Brighton, and during the same half hour. In no two cases was the weight recorded the same. Another was weighed on two scales in different branches of the same cash chemists, whose watchword is, like all other chemists', prescriptive accuracy; the results were again different. To-day, within a quarter of an hour, I have been weighed on the scales of five chemists' shops in Chatham; in every case the recorded weight is different. I enclose the weight certificates which were given to me and which show the variations. During the past two years I have had occasion to be weighed in many towns in the south of England, and everywhere I have found the same inaccuracy. Is it because the chemists themselves receive no payment for the operation—as this is usually given to the local hospital—that the scales are allowed to be everywhere so scandalously out of order? Why do the inspectors of weights and measures omit to test them, especially as the results recorded mean so much to the health and spirits of the patients?

I am, Sir, yours faithfully,

(Rev.) John G. Morton.

St. Andrew's Presbyterian Church, Chatham.

*** The five weight certificates, which all bear the same date, read 13 st. 3 lb., 13 st. 3 lb. 12 oz., 13 st. 4 lb., 13 st. 4 lb. 8 oz., and 13 st. 5 lb., the maximum variation being 1·08 per cent. of the total weight.—Ed. L.

## STANDARDISED ANALYTICAL REAGENTS.

The British Drug Houses have followed the example set by other similar firms in producing in book form[1] the various tests of purity in connexion with their series of analytical reagents. The volume is of the familiar type, and it describes tests on the 88 substances included in every analytical reagent list. The work has been thoroughly undertaken, and the result is a most useful volume. In addition to the information usually contained in such books, the compilers have included methods for the estimation of the majority of the substances. The value of the book is considerably enhanced by a list of reagent solutions and also by a very full index.

ON THE

# DEVELOPMENT OF PSYCHO-PATHOLOGY

AND ITS PLACE IN MEDICINE.

*Delivered at the Royal College of Physicians of London on March 11th, 16th, and 18th, 1926,*

By BERNARD HART, M.D., F.R.C.P. Lond.,
PHYSICIAN IN PSYCHOLOGICAL MEDICINE, UNIVERSITY COLLEGE HOSPITAL.

## LECTURE III.*

In the preceding lecture the basic conceptions underlying Freud's theories were briefly considered, and the conclusion reached that their scientific validity could only be determined by an examination of the observed facts upon which they are based. An attempt must be made here to indicate the lines along which such an examination should be directed, but before passing on to this task it will be advisable to trace Freud's sex theories through a further stage in their development, as a better understanding of the part assigned to sex and libido in the modern Freudian system will thereby be attained. This further stage is characterised by the incorporation of the conception of "narcissism," and its history lies along two lines of research, the investigation of dementia præcox and of the psychoneuroses of the war.

### The Conception of Narcissism.

The psycho-analytic investigation of dementia præcox had been to some extent foreshadowed by Freud, but the first systematic study along these lines was due to Jung, who in 1907 published his well-known "Psychologie der Dementia Præcox." He showed that many of the symptoms of dementia præcox closely resembled those met with in hysteria and were explicable by almost identical mechanisms, yet they differed from the latter in their fixity and immutability. This characteristic inaccessibility was further investigated in the light of Freud's libido theory, and was seen to be associated with an absolute incapacity for "transference," that is to say, the peculiar affective relationship between physician and patient upon which all therapy was conceived to depend. As a result of subsequent work conceptions were devised by which the inaccessibility of the dementia præcox patient was brought definitely into relation with the libido theory, and the theory itself considerably modified and extended. It was held that the earlier stages of sex development included a phase in which the libido was directed on to the individuals own "ego." This phase, in which the ego might be said to constitute the "object" of the libido, preceded the phases in which an object was sought in the outer world, and to its manifestations the name of "narcissism" was given. Dementia præcox could then be conceived as involving a regression to the narcissistic stage of sex development, just as the psychoneuroses were regarded as involving regressions to other and later stages of that development. In this way the familiar features of dementia præcox, its curious shut-in character, its divorce from reality, the inaccessibility of the patient, and his tendency to live in a phantasy of his own making, could be explained as direct results of the attachment of the libido to the ego, and its consequent imperviousness to the claims of the external world. And in this way also dementia præcox could be subsumed under that interplay of the libido and the ego which has come to be more and more the central point of the Freudian theories.

During the recent war a great mass of illness occurred which, christened at first by the misleading name of "shell shock," came ultimately to be known as the psychoneuroses of war. This change of nomenclature was due to the rapidly won recognition of the psychological origin of these conditions. Indeed, it may be said that, whatever else the war has done, it has at least conclusively demonstrated the existence and importance of psychogenic disorder. It was observed that the psychoneuroses of war, although naturally coloured in their symptomatology by the peculiar circumstances of their origin, did not differ in essentials from the psychoneuroses already familiar in civil life. Moreover, investigators noted that the mechanisms which Freud claimed to be responsible for psychoneurotic symptoms were remarkably applicable to the war conditions, and that they were in fact much more obvious and easily demonstrated in the latter, doubtless because of their relatively rapid development and simple character. There seemed to be no doubt that an intrapsychic conflict was at the bottom of the war psychoneuroses, and one which produced its effects according to laws identical with those already described by Freud. Yet the conflicting forces had apparently no relation to sex, but were manifestly concerned with instincts of a totally different character, in particular those ministering to self-preservation. The general effect of these observations was to confirm in a high degree Freud's conceptions of mechanisms, while they threw grave doubt upon his generalisation that psychoneuroses invariably involved the sex instincts and were the result of fixations and regressions in the action of the libido. The Freudian school, however, endeavoured to save the position by an application of their new conception of narcissism. The part apparently played in the war psychoneuroses by the instincts of self-preservation was reduced to a manifestation of narcissism, and thus the conflicts which overtly had no relation to sex were brought within the general theory of the libido and its development.

Freud has always insisted, even in his earliest work, that he was attaching to sex a wider significance than that with which it was generally credited. It is clear, however, that in the developments we have just considered, its application has been extended to a far more comprehensive sphere than was contemplated in the original theories. These developments are, indeed, a particular instance of an evolution which characterises the whole of the later growth of the psycho-analytical doctrines. The libido theory has been pushed into further and further fields, and the manifestations of the libido are now held to include not merely normal sex activity, perverted sex activity, and the psychoneuroses, but a vast mass of human thought and behaviour. Freud's early generalisation that no neuroses can be present with a normal sexual life has been submerged in an immensely wider generalisation which, though not explicitly stated, might be said to run, "Without processes having their origin in sexual life the greater part of human activity would cease to exist." As psycho-analytical investigation proceeds, more and more of the behaviour of man is brought under the general conception of the interplay of libido and ego, and it is perhaps not unreasonable to assume that the aim in view is to bring the whole of such behaviour under it. In other words, Freud's theories have moved far beyond the department of medicine in which they had their origin. The position now is that the permutations of the libido account for a great number of the phenomena of life, and certain permutations account for some of the phenomena of disease.

We may pause to examine this wide conception, and to consider whether it is inherently possible or justifiable. To begin with it may be noted that, although the attempt to subsume so much of human activity under a single principle naturally arouses immediate criticism, it is not in itself absurd, and is indeed supported by certain general considerations. Drever has remarked that "though perceptual experience is more and more overlaid by the higher mental processes, it always underlies them, and, though control of primitive impulse becomes more and more complex, it is always a control by that which draws its controlling force, ultimately and fundamentally, from primitive impulses, never a control *ab extra*."[1] Pursuing this line of thought it may be said that, if we are to dissect mental processes into constituent parts, and to trace back the driving forces to their elements, the latter must presumably consist of something like the primitive instincts. Similarly, if we accept an evolutionary standpoint, we must build up man's activities from elements to be observed in lower animals, and sex and self-preservation would constitute the chief founts from which energy could ultimately be derived. It is not therefore impossible, or even improbable, that a conception will finally be achieved in which the manifold activities of man are reduced to primitive forces, and shown to be the result of permutations and combinations amongst those forces. These considerations serve to show that Freud's attempt is at any rate legitimately conceived, but whether it is a successful attempt is, of course, another matter. We may conclude that here, as in the case of the other conceptions we have examined, a priori objections have no weight, and that the whole structure of Freud's work can only be appraised by a careful examination of the facts upon which it is based, and a determination of the extent to which the concepts proposed can be confirmed and verified by those facts.

---

* Lectures I. and II. appeared in The Lancet of March 20th and April 3rd respectively.

The application of criticism along such lines is made easier by the circumstance that these are precisely the criteria by which Freud himself is prepared to abide. He has pointed out that "psycho-analytical investigation could not, like a philosophical system, make its appearance with a complete and ready system of doctrine, but had to build up step by step the way to the understanding of psychical complications by the analytic dissection of normal and abnormal phenomena."[2] In other words, the claim is made that psycho-analytical theory is a direct induction from observed facts, and must stand or fall with the accuracy of the facts and the validity of the induction. Such a claim is a legitimate appeal to the bar of science, and justifiable criticism can only concern itself with two questions: (1) are the facts as stated? (2) are the concepts built up thereon valid?

The first question leads us to the kernel of the matter at issue, and discloses at once the strength and the weakness of the psycho-analytic position. The contention is put forward that anyone who will investigate a case by Freud's method will find that *the facts observed are as Freud states them to be*, and it might appear that if this contention could be established the foundations of psycho-analytical theory would be placed beyond dispute. Now there is undoubtedly considerable evidence in support of this statement, though not perhaps that overwhelming evidence which would serve completely to justify it. It may be accepted that the great majority of those who have examined cases by Freud's method have confirmed his observed facts, and this applies even to observers such as Jung, who have drawn from those facts conclusions very different from those of Freud. Yet this acceptance has by no means that complete confirmatory significance which it at first sight appears to carry. We note that the facts are observed by the aid of a particular method, and until we have carefully examined the nature of this method and its reliability as a weapon of investigation, the value of the facts ascertained by its use cannot be satisfactorily determined, even if it could be shown that all the users of this method have *observed identical phenomena*.

### THE METHOD OF PSYCHO-ANALYSIS.

The method whereby the facts, upon which Freud relies for the building of his theories, are elicited, is the method of psycho-analysis. The patient talks freely about any subject which occurs to him, avoiding so far as possible any deliberate attempt to control or direct the flow of his associations. It is held that these associations are largely conditioned by forces of which the patient is unconscious, and the physician, from his knowledge of mental mechanisms, is enabled to deduce from the material provided by the patient, and the manner of its presentation, the nature and mode of action of the factors responsible for it. These conclusions are utilised by the physician to point out to the patient the significance of certain of his thoughts, to direct his attention to others, and so to push the investigation until the unconscious factors are fully brought into the light of consciousness. Freud has himself described the process in these words: "The patient talks, tells of his past experiences and present impressions, complains, and expresses his wishes and his emotions. The physician listens, attempts to direct the patient's thought processes, reminds him, forces his attention in certain directions, gives him explanations and observes the reactions of understanding or denial thus evoked."[3] Later, on the same page, he remarks that the patient "will make the communications necessary to the analysis only under the conditions of a special affective relationship to the physician," the so-called "transference."

### OBJECTIONS TO THE RELIABILITY OF PSYCHO-ANALYSIS.

Now this is admittedly the method by which the facts of psycho-analysis are obtained, and an examination of its character seems to call for a considerable modification of the claim that psycho-analytical theory is based upon facts of observation. It is true that the theory is based on "facts," but these facts are not obtained by simple observation; they are reached by the employment of the method of psycho-analysis. This method intervenes, as it were, between the actual facts of observation and the prepared facts upon which the concepts are based, and it is of such a nature that the possibility of distortion cannot with certainty be excluded.

It has become a commonplace of psychology that the direction of thought, and its content, are influenced in a remarkable manner by factors of an affective order, and it is clear that such influences are at least possible in the method of psycho-analysis. Before we can be satisfied that the communications of the patient, which constitute the facts of observation of psycho-analysis, are of the kind to which the term "fact of observation" is customarily applied in other branches of science, we must be satisfied either that they are not distorted by the method of investigation employed, or that the degree and direction of the distortion can be accurately estimated. An attempt to apply this test to psycho-analytical research will be rendered easier by a preliminary review of the knowledge we possess concerning the potential sources of such distortion.

The problem of the value of human evidence—that is to say, the objective accuracy to be credited to communications made by one person to another concerning matters of fact—aroused considerable interest amongst psychologists in the earlier years of the present century. It had been previously noted by historians that the old standard whereby the moral character of a witness was taken as the sole test of his reliability, and his statements held to be accurate if his honesty was established, was inadequate and misleading. It was apparent that, quite apart from his honesty, his statements might be perverted by all kinds of factors of whose action he was completely unconscious. Binet, in 1900, called attention to "the advantage that would accrue from the creation of a practical science of testimony,"[4] and the suggestion was enthusiastically taken up by Stern,[5] of Breslau, who with his fellow-workers carried out an immense amount of painstaking research. Extensive experiments were devised, consisting essentially in the submitting of a predetermined experience to a number of subjects, and subsequently obtaining from them an account of what they had observed. The results were remarkable, and showed conclusively that a witness's report of his experience, even when given with the utmost honesty and conscientiousness, is rarely completely correct, and that a proportion of the details, including even those of whose truth the witness is absolutely certain, are erroneous. Thus in Borst's experiments only 75 per cent. of the items of which the witness was certain were in fact accurate.[6] If, instead of being asked simply to narrate what he had observed, the witness were interrogated with regard to details, accuracy was greatly diminished, though the range of facts apparently remembered was increased. This result is presumably to be attributed to the suggestive influence of the questions asked.

". . . dass die psychoanalytische Forschung nicht wie ein philosophisches System mit einem vollständigen und fertigen Lehrgebäude auftreten konnte, sondern sich den Weg zum Verständnis der seelischen Komplikationen schrittweise durch die analytische Zergliederung normaler wie abnormer Phänomene bahnen musste."

[3] Freud: Introductory Lectures on Psycho-analysis, English translation, 1922, p. 13.

The mechanisms responsible for these perversions of memory were studied by observers who noted the influence of preconceptions, suggestion, and various other factors. Investigations of definitely pathological phenomena showed that extraordinary memory distortions may occur, such as the confabulations of the hysteric and the alcoholic, and the remarkable production of false reminiscences in the condition known as "pseudologia phantastica." Here the action of suggestion and other emotional forces was clearly demonstrable, and it was not difficult to show that the factors producing these exaggerated pathological effects were also active, though in a lesser degree, within the limits of the normal, and certainly capable of causing marked perversions. The conclusion to which all these various observations lead is that memory is an instrument whose reliability can be grossly disturbed by a multitude of factors, that no certain line between actual reminiscence and phantasy can be drawn except by some measure of objective verification, and that in the absence of such means a patient's statements concerning events of his past life *can only be accepted* with considerable reserve.

Freud is, of course, well acquainted with the facts we have enumerated, and with the potential capacity for distortion inherent in human memory. He was, indeed, one of the first to appreciate clearly the difficulty of distinguishing between phantasies and genuine reminiscences, and it was this recognition that led him to abandon his original theory that the psychoneuroses were the result of psychic *traumata*. He discovered that in many cases the traumatic event, which was apparently responsible for the subsequent disorder, had in fact never taken place, and was merely a phantasy constructed by the patient's mind. In such cases the clinical picture was nevertheless essentially identical with that observed where the "traumatic" event could be objectively verified, and the conclusion was therefore inevitable that the specific causal factors could not lie in the event, but in the mentality of the patient. Freud held that under these circumstances the objective validity of the memories produced by the patient was of relatively minor importance; he was concerned with the detection of intrapsychic forces, and for this purpose phantasies provided a material even more useful than genuine memories. Similarly, in the case of dreams, whether a patient actually dreamt a dream as he related it, or unwittingly elaborated it *on waking into* an appreciably different structure, mattered but little to the work of interpretation, because in both cases the same forces were at work, and it was the discovery of those forces which constituted the problem at issue. This contention is applicable to the material produced during a psycho-analysis, and goes some way towards meeting the objections we have cited concerning the validity of that material. It is, indeed, a sound contention so far as the distorting forces arising within the patient's own mind are concerned. These would influence the flow of thought, but would by this very circumstance provide the necessary ground for their detection, and we should have no reason to deny to the flow of thought the title of "fact of observation," although the patient might be relating phantasies rather than actual memories. It is quite another matter, however, when the flow of thought is not influenced by purely intrapsychic factors, but by the intervention of the psycho-analyst. Under these circumstances the "memories" produced may be conditioned to a very significant extent by factors which lie entirely outside the patient, and the question of their value as indicators of the trends existing in the patient's mind assumes an altogether different aspect.

Moreover, the problem at issue is not merely concerned with memory. The whole direction and content of the patient's psychic processes are alterable by factors of the same kind as those observed in the case of memory. A lengthy investigation of a patient's mind means that one is no longer examining at the end of the investigation the object which one set out to observe, but an object which has progressively altered during the course of the investigation, and altered in a way which may have been largely determined by the investigation itself. This was the circumstance which vitiated absolutely and completely the painstaking conclusions drawn by Charcot and his school from the phenomena observed in the trained hysterics of the Salpêtrière. A perusal of the literature of double personality suggests strongly the existence of a similar vitiating factor, and in a case of this kind which I was personally able to investigate I had no difficulty in satisfying myself that much of the symptomatology observed was a direct result of the process of investigation employed.[7] It is not easy to avoid the conclusion that the method of psycho-analysis contains potential sources of distortion at least as great as those in the instances just mentioned. The preconceptions of the analyst, the particular moments at which he sees fit to intervene in the patient's narrative, the emphasis which he directs to certain features of the narrative, the point at which he deems a flow of associations to have reached a significant element, all these are abundantly able to produce decided alterations in the subsequent *functioning of the patient's* mind. It must be remembered, moreover, that psycho-analysis is a lengthy process, and that very small changes of direction in a long course may lead ultimately to a wide divergence. When the majority of the changes of direction tend to be in the same sense, as they are likely to be in investigations conducted by analysts trained in a particular system of beliefs and technique, then it is not surprising that the final pictures attained bear a close similarity. It *may be noted* in this connexion that, while the pupils of Freud confirm by their clinical observations the findings of their master, the pupils of Jung, working with weapons forged of much the same material and in a closely similar pattern, have no difficulty in finding ample clinical confirmation for the quite disparate tenets of Jung.

These objections to the reliability of psycho-analysis as a means of investigation are *of a grave* character, and make it impossible to accept the contention that Freud's theories are based on facts of observation if the term "fact of observation" is given the significance which it possesses in other branches of science. Moreover, if the facts of observation are not beyond question, the conceptions and theories built upon them cannot be solidly constructed according to the canons of scientific method, and it is not possible to stamp them with the hall-mark of science unless and until the means by which they have been obtained has been shown to be trustworthy. The claim has been put forward that an inquirer can convince himself of the validity of the method of psycho-analysis by the process of having himself analysed, but clearly this claim can have no weight when the problem at issue is the determination of the reliability of the method itself. The attainment of an inner conviction is a phenomenon belonging to the sphere of religion, and without relevance to science; its existence may attest the spiritual or æsthetic value of its object, but not its right to be incorporated into scientific knowledge. The latter right can only be gained by rigid objective verification and demonstration, and not in the least by subjective convictions.[8]

[7] Bernard Hart: A Case of Double Personality, Jour. of Mental Science, 1912.

The claim that a person desiring to practise psycho-analysis must himself first be analysed in order to acquire the necessary technique is, of course, on an altogether different footing, and seems to be perfectly legitimate. It is perhaps also legitimate to require that the intending practitioner should undergo personal analysis to the end that he shall overcome his own "resistances," which would otherwise distort his judgment of the patient's mental processes. Clearly, however, this requirement can only be defended as a means of improving technique in a method already established, and it can contribute nothing to the demonstration of the validity of psycho-analytic method itself. On the contrary, the existence of such a claim inevitably strengthens the criticism which asserts that the trained preconceptions of the analyst play a part in fashioning the material produced by the patient. This criticism receives a further justification when we note that the followers of Jung, whose theories differ fundamentally from those of Freud, make a similar claim that the practitioner of their method must undergo a personal analysis, of course by a member of Jung's school, before he attempts to deal with the problems of his patient.[9]

In spite of the importance and weight of these various objections there are two points to be brought forward which serve to weaken their force. The first point is that psycho-analysis has a long history behind it, and many of its earlier discoveries were made by a process much less open to criticism than the method we have described in words quoted from one of Freud's later works. In these instances the intervention of the analyst was reduced to a minimum, and the "facts of observation" approximated much more nearly to the standard which science demands. A number of the more elementary Freudian conceptions and theories are solidly built upon facts of this character; they have attained a wide acceptance, and it is not unreasonable to regard them as established contributions to our knowledge. Moreover, it is necessary to emphasise that these comparatively elementary conceptions are nevertheless of the first importance, and have cast more light on the problem of nervous disorder than the work of any other psychopathologist, whatever the verdict history may ultimately pass upon the later theories and practice of Freud. In view of these circumstances psycho-analysts might naturally claim that the elementary and earlier conceptions are the groundwork upon which their later methods are constructed, and that if the former are valid, so also are these later methods. It is, nevertheless, difficult to accept this contention, because, although the margin of potential error in the elementary conceptions is relatively small, it becomes greater and greater the more an imperfect method is employed, unless it is possible to obtain objective verification by a frequent resort to the plane of phenomenal fact. This constant testing by an appeal to objective facts is a sine qua non in the development of any scientific theory, and we have seen that it is just this test which is lacking in the growth of psycho-analytical theory, because objective facts will not serve its purpose, but only those facts after they have been prepared by the method of psycho-analysis.

These considerations lead us on to the second point which serves to weaken the objections cited to the method of psycho-analysis. It is true that the facts are not of the order to which the facts of observation of other sciences belong, but this character appertains in some degree to all the facts of psychology. Except for the facts of introspection all other psychological facts are inferences. The only direct observation possible is observation of behaviour, of action, or of speech; in order to deal with these facts by the psychological method it is necessary to go behind them to the underlying subjective experience, which cannot be directly observed, but only inferred from the behaviour facts. In this way a new series of "facts" is obtained upon which the psychological concepts are ultimately constructed. This peculiarity of the method of psychology has been emphasised by Drever, who regards it as an inherent weakness, and one which dooms psychology to occupy always an invidious position in the scientific hierarchy, so that explanation of a particular series of phenomena by the concepts of another branch of science will always be accepted in preference to a psychological explanation, if both are available.[10]

Moreover, although the facts of introspection are observed with a directness and intimacy greater than that attaching to the facts of any other science, yet they are by their intrinsic character incapable of objective verification, and we already know that they are subject to numberless sources of error unless they are made in a sphere in which emotional and other distorting factors are unlikely to play a part. It is objective verification which science insistently demands, and owing to the nature of its material psychology can only give an inadequate response to that demand. The objection on this score which has been taken to the method of psycho-analysis is therefore applicable to the whole sphere of psychological research. Nevertheless, there are degrees of deviation from the strict canon of scientific method. It may be true that every psychological conception rests upon facts which are separated from actual facts of observation by some measure of inference, but in many such conceptions that measure of inference is very small. In Janet's conception of dissociation, for example, the degree of inference is so slight that it may safely be neglected, and a similar statement is perhaps applicable to the more elementary Freudian conceptions, but in the elaborate later theories the actual facts of observation become more and more remote, and the degree of inference swells by progressive accretions until a satisfactory objective verification is no longer possible.

We are, therefore, compelled to regard the method of psycho-analysis as an imperfect weapon of investigation, and one capable of seriously distorting the facts which it elicits. Those facts, and a fortiori the conceptions built upon those facts, must hence be accepted only with reserve unless other sources of confirmation are available lying altogether outside the evidence furnished by the employment of the method itself. A number of such external sources of confirmation have been put forward, and these now call for some consideration.

---

[8] Freud has himself considered the criticism that the admitted influence of the physician upon the patient casts doubt on the objective validity of the findings of psycho-analysis, in his Introductory Lectures on Psycho-analysis, English translation, 1922, p. 378. He holds that this criticism is more satisfactorily refuted by the evidence of experience than by the aid of theory, and that "Anyone who has himself conducted psycho-analyses has been able to convince himself numberless times that it is impossible to suggest things to a patient in this way." This would seem, however, to be a further resort to the "inner convictions" produced in the analyst as a ground for accepting the validity of his beliefs. It is, of course, possible to contend that in the sphere of psycho-analysis strictly objective verification is impracticable, and that a subjective verification is all that can be obtained, but such a contention would imply a decisive abandonment of the claim that psycho-analytic investigation satisfies the standards demanded by science. Freud's further arguments, relating to the verification afforded by therapeutics and the study of the insane, will be considered later.

### THERAPEUTIC RESULTS OF PSYCHO-ANALYSIS.

The first confirmation proposed is that derived from the therapeutic results. Many of those who practise psycho-analysis formerly employed other methods such as suggestion and persuasion, and they maintain that the cures now achieved are much more extensive and permanent. The conclusion is drawn that, if a case treated by psycho-analysis recovers, this circumstance affords proof of the accuracy and adequacy of the method used. Unfortunately, this argument has but little weight. In the history of medicine many structures have been built upon the fallacy of post hoc ergo propter hoc, and an appreciation of its significance and potency would no doubt shake other departments of medicine than that with which we are here concerned. In this department, however, its incidence and effects are peculiarly disconcerting and difficult to appraise. It is, of course, true that satisfactory results are achieved by psycho-analysis, but it is equally true that satisfactory results are achieved by many, indeed by all, other methods of psychotherapy, and by a multitude of methods which lie altogether outside the walls of orthodox medicine. Moreover, if it be conceded that the cure is a direct result of the treatment, there remains considerable doubt as to the precise factors to which this result is to be ascribed, and it is possible that these do not belong to the essential structure of the method employed, but are merely vicariously associated therewith. For example, it is extremely difficult to delimit the results produced by faith and suggestion, and unless the activity of factors of these kinds can be accurately estimated, no certain conclusions can be drawn as to the efficacy of therapeutic methods into which such factors may enter.[11]

The Freudian school does not deny that a factor of the order of suggestion enters into psycho-analysis; on the contrary, its existence is an essential part of their tenets. This factor is the peculiar affective relationship which develops between the patient and the physician, and upon it the "transference" processes, which are conceived to be a necessary part of the therapeutic action, are dependent. Freud expresses this affective relationship in terms of his libido theory, and believes it to derive its driving power from the psychosexual forces existing in the patient. He regards all forms of psychotherapy as involving this relationship, including those grouped under suggestion. He holds, indeed, that "A human being is . . . on the whole only accessible to influence, even on the intellectual side, in so far as he is capable of investing objects with libido,"[12] and that this capacity distinguishes the psychoneuroses which can be treated from those conditions, such as dementia præcox, in which therapy is impotent because libidinous occupation with an object, and hence the necessary affective relationship to the physician, cannot develop.

It is admitted, therefore, that an affective relationship, essentially identical with that underlying suggestive therapy, necessarily occurs in the course of psycho-analysis, and is indeed an integral constituent of the curative process. The psycho-analytical school maintains, however, that this affective relationship is not allowed to dominate the whole course of the treatment, as it is in the case of suggestive therapy, but that at a certain stage it is itself submitted to analytic dissection and finally dissolved. If this contention be correct it is clear that the accurate estimation of the results to be ascribed to suggestion, which we postulated as a necessary pre-requisite before conclusions as to the therapeutic efficacy of psycho-analysis could be drawn, would immediately become possible. This contention is based, however, upon facts observed by the employment of the method of psycho-analysis, and its validity is entirely dependent upon the validity of this method. It can play no part, therefore, in a discussion in which the validity of the psycho-analytic method is itself the problem at issue, unless we are to be guilty of argument in a circle.

We must hence conclude that the argument from therapeutic results cannot provide the independent confirmation of psycho-analytic validity of which we are in search. It may be remarked here, however, that the opposing argument, which seeks to disprove psycho-analytic doctrine by the enumeration of alleged failures or harmful results, has still less weight. Quite apart from the inadequate and obviously biased character of much of the evidence put forward, it is clear that here again the fallacy of post hoc ergo propter hoc is once more playing a potent part. To ascribe an unfortunate sequel to the method of treatment employed rather than to the disease itself assumes an exact knowledge of the nature and interaction of the complex factors involved which we are very far from possessing, and such a conclusion cannot be justified until that knowledge is attained. Moreover, even if it could be demonstrated that the sequel was the direct result of the method, this would but bear witness to the potency of the method, and it has frequently been pointed out that a remedy which is incapable of doing harm is hardly likely to be capable of doing good.

### THE BEARING OF MYTHS AND FOLK-LORE ON PSYCHO-ANALYSIS.

The second sphere in which it is alleged that confirmation of the findings of psycho-analysis can be obtained is the study of myths and folk-lore. It is maintained that there are to be found here human creations clearly exemplifying the processes which have been elicited in the individual by the method of psycho-analysis. A prodigious amount of research has been carried out in these fields by Freud's adherents, and the conclusions reached have been generally in accord with the principles of psycho-analysis. It is difficult to estimate the precise validity of these conclusions, because the actual objective facts observed in the research are admixed with a multitude of inferred facts of the kind peculiar to the psycho-analytic method, and anthropologists of other schools are by no means in agreement as to the deductions which may properly be drawn. We may admit, however, that the objective facts in this sphere do provide formidable arguments in favour of at any rate some of the findings of psycho-analysis.

### INSANITY AND PSYCHO-ANALYSIS.

The third sphere in which confirmation of psycho-analytic doctrine is to be found is that of insanity. The evidence here is, perhaps, more convincing than in any other field, because phenomena can be observed in the speech and actions of the insane which are entirely conformable to the principles deduced by the psycho-analytic method, and in which any influencing of the patient by the physician is excluded by the nature of the case. MacCurdy has emphasised the strength of this evidence in a passage which at the same time acknowledges the inherent weakness of the psycho-analytic method, and this passage deserves quotation. "Everyone knows that preconceptions determine observations very largely in all scientific work. We see what we are on the look out for, and are blind to the unexpected. In psycho-analysis, however, this danger is augmented by the plasticity of the material which is largely produced in accordance with the theory of the analyst. With this condition of affairs it seems extraordinary that Freud should, during the years when he was making his discoveries, have kept his eyes so vigilantly open for new factors and now unconscious phenomena, and that his general conclusions as to the content of the unconscious should be so accurately confirmed by examination of the insane who do not talk or dream to order."[13]

---

[11] T. A. Ross, in his book The Common Neuroses, 1923, p. 7 ff, describes the various methods of treatment he has successively employed during his career as a psychotherapist, and points out that with each he obtained good results so long as, and only so long as, he himself believed in its accuracy and value.

[12] Freud: Introductory Lectures on Psycho-analysis, English translation, 1922, p. 373.

### GENERAL CRITICISM OF THE FREUDIAN THEORIES.

We may now endeavour to summarise our review of the Freudian theories. The criticism which has been levelled at the conception of the unconscious and other of Freud's basic assumptions on the ground that these are impossible entities is due to a misapprehension of the nature of science and of the psychological method of approach. The validity of these conceptions, as in the case of all scientific conceptions, can only be determined by an appraisement or recapitulation of the objective facts and the testing of the theories in the light of these facts. The real weakness of the Freudian theories depends upon the imperfections of the method of psycho-analysis as a weapon of investigation, whereby the conceptions rest on inferred facts rather than on actual objective facts. This weakness is inherent in some degree in all psychological research, but it is graver here, because the deviation from observed facts to inferred facts is exceptionally great, and introduces numerous potentialities of distortion. Moreover, these potentialities are much increased by the circumstance that the method of psycho-analysis may, owing to its peculiar nature, continuously alter the objective facts during the course of the analysis. Nevertheless, many of the simpler conceptions are based on inductions in which both the measure of inference and the possibility of distortion by the method of investigation are both comparatively small. Further, there are sources of confirmation outside the method of psycho-analysis which, at any rate, give some support to the conceptions. We may draw the final conclusion that, although the theories of Freud do not attain the standard demanded by the canons of science, some of his conceptions approximate very nearly to that standard, and perhaps as nearly as any psychological conception can approach. A consideration of the immense advantage to be gained from the introduction of a conceptual psychology as opposed to a mere description of mental processes, together with a due appreciation of the almost insuperable difficulty of obtaining satisfactory objective verification in this sphere, suggest that some deviation from the strict *path of scientific induction must necessarily be allowed*, if we are not to abandon all hope of progress. The danger of such deviation must always be borne in mind, however, and it must not be forgotten that subjective feelings of certainty in the followers of Freud are no substitute for the objective verifications which science must insistently demand. The solidity of the foundations is vastly more important than meticulous additions to the upper stories, and we may reasonably ask for every possible means of investigation to be directed to the method of psycho-analysis in itself, with a view to establishing its validity, and eliminating or controlling the sources of error which seem to be inherent in it.

The later publications of Freud culminating in "Das Ich und das Es," published in 1923, have not been considered. The keynotes of this later work may, perhaps, be said to be an alteration in the direction of inquiry from the libido to the ego, an attempt to analyse and define the properties of the latter, and various speculations concerning the fundamental forces of the mind. None of this work could be made intelligible without entering into a degree of detail quite impossible here. For our present purpose it will suffice to note that the investigations do not essentially alter the earlier findings, but *superimpose additional* stories upon the older building, so that their validity is necessarily dependent upon that of the underlying structure. A further ground for criticism, however, may be mentioned. The later work of the Freudian school with its minute dissection of the libido and the ego into constituent parts, which combine and interact in various ways, introduces a mass of conceptual entities which approximate in their form to those of chemistry and physics.[14] Now, it cannot be questioned that conceptual entities of this type can be legitimately employed if a stringent relationship to observed fact is rigidly maintained, but when they are reached by the extensive use of a spatial and mechanical metaphor, which can only be applied in the sphere of psychology by the exercise of some ingenuity and force, it is necessary to bear in mind the dangers which beset the road. The construction of such conceptions may, no doubt, indicate that psychology and psychopathology are attaining the precision and exactness of the mechanistic sciences, but it must be admitted that the philosophy of Pythagoras produced concepts which also appear to be precise and exact, and we need to be very sure in which of these fundamentally different directions we are travelling. The essential criterion lies in the relationship to the plane of observed facts. The concepts of mechanistic science are verifiable by a constant dipping to the level of experience and experiment; the speculations of Pythagoras can be submitted to no such test. The psycho-analytic school, of course, claim that this criterion is applicable to their work, and that the conceptions they put forward are legitimately built upon clinical observation. We are, therefore, led back again to the problem of the validity of the method by which these observations are made, and to the cardinal necessity of establishing that method, before we can feel any security in the many-storied structures which are now being built by their aid.

### THE SCHOOLS OF ADLER AND JUNG.

The genius of Freud has produced a profound effect upon the development of psychopathology. In addition to the orthodox school of psycho-analysis, which follows more or less rigidly the path sanctioned by its founder, a multitude of other investigators have been materially influenced by Freud's conceptions. Many of these investigators are prepared to travel a certain distance with Freud, although they refuse to accept his views in their totality. Others incorporate individual psycho-analytic conceptions in theories mainly built on other lines, as we have seen to be the case with certain persuasionist and suggestionist practitioners of the present day. None of these writers call for individual mention here, as they do not add anything essentially new to the principles we have already discussed, but merely adopt an eclectic attitude with regard to them. Two schools of thought, however, must be specifically considered, because, although they were both founded by men who were originally followers of Freud, they have now radically diverged from the orthodox path of psycho-analysis. These are the schools of Adler and of Jung.

Adler's views bear a broad general resemblance to the earlier Freudian theories from which they emerged, except that he finds the *driving forces* responsible for the neuroses and other mental phenomena not in the sphere of sex, but in the will to power.[15] The precise character of these conceptions cannot be discussed here, but it may be noted that the method of investigation employed and the validity of the conclusions reached are open to all the objections which we have brought forward in the case of the psycho-analytical theories proper. It need only be remarked that the doubts we have expressed as to the scientific trustworthiness of the method of psycho-analysis cannot but be enhanced when we observe the remarkably discrepant results achieved by it in the hands of men who start with different preconceptions.

Jung's work is of very great interest and importance. Its chief tenets may be described as follows: A denial of the paramount significance of sex, and the substituting of the exclusively sexual libido of Freud by an undifferentiated libido having the significance of a general psychic energy, and capable of expressing itself through any channel of human interest and endeavour; the doctrine that the unconscious includes a collective element common to the race in addition to its personal content; a theory of the psychoneuroses which, although it accepts the Freudian view that the basis of these disorders lies in intrapsychic conflict, radically differs therefrom in its interpretation of the forces engaged and their mode of action. Finally, there is in Jung's conceptions a significant change in the general attitude and in the angle of attack. He insists that a simple reduction of mental processes to their causal elements is inadequate, and that they can only be understood if their teleological and prospective significance is taken into account; and that the symbols found in dreams and elsewhere are not merely "a sign of something repressed and concealed, but at the same time an attempt to comprehend and to point out the way of the further psychological development of the individual."[16]

---

[13] MacCurdy: Problems in Dynamic Psychology, 1923, p. 132.

[14] See, for example, the theory of suggestion formulated by Dr. Ernest Jones in his paper The Nature of Auto-Suggestion, Brit. Jour. of Med. Psychol., 1923, p. 208.

[15] Adler's theories were originally developed in Studie über Minderwertigkeit von Organen, 1907, and Über den nervösen Charakter, 1912, both of which have been translated into English. A number of later works have since appeared, including Individual Psychology, English translation, 1925.

To consider the scientific validity of these various views would clearly be a formidable task, but we are fortunately relieved of the necessity of undertaking it by Jung's frank admission that his work does not satisfy the canons of science.[17] This admission is based partly on the contention that "purpose" cannot be included in the structure of science because it is opposed to the principle of causality upon which scientific method necessarily depends. We have seen that this contention is disputable, that "purpose" can be included in causality in a wider sense, and that a purposive psychology can therefore be built within the method of science, although it cannot contain the reversible sequences of mechanistic science.[18] Apart from this point, however, Jung's methods are certainly in part extra-scientific, and indicate a reversion to that admixture of psychology with the viewpoints of philosophy, ethics, and religion, which characterised the speculations of older days. But it is important to note that the admixture here is not due to a confusion of thought or a failure to distinguish the functions of the various disciplines, but is deliberately selected as likely to add most to human knowledge.

This is the chief interest of Jung's work in relation to the subject of the present lectures. It expresses a revolt against the view that the method of science must be the paramount arbiter of human knowledge, and attempts to substitute for this the principle that, while human life and thought cannot be explained by concepts belonging to science, they can be explained by other modes of attack. The question at issue is no longer whether psychology is capable of achieving the necessary standards of science, but whether science is capable of fulfilling the requirements of psychology. This is a bold step, but there is a good deal to be said in its justification. MacFie Campbell has remarked: "We are too much accustomed to think that there is only one correct way of dealing with experience, and that the angle, from which we personally come to experience, is the only one from which it can be approached. . . . The results and methods of others we are liable to see only as mistake and error, instead of merely as another way of dealing with experience."[19] It is here that the essential antithesis lies between the doctrines of Jung and of Freud. While Jung abandons science as incapable of dealing adequately with the problems of psychology, Freud strives to keep within its bounds. Moreover, in Freud's later work his conceptions approximate in their form to those of the mechanistic sciences, and the divergence from the point of view of Jung becomes still more marked. We have seen that there is some reason to question how far Freud has achieved success in this aim, but, even if success be admitted, Jung's attitude is a reminder that the method of science may conceivably not be the only weapon whereby the field of psychology can be attacked, and that it may ultimately prove to be an ill-adapted and essentially inadequate weapon. Dr. T. W. Mitchell, in a review of Freud's "Beyond the Pleasure Principle," says: "The pessimism which hangs like a cloud over the whole of this essay is perhaps the inevitable outcome of a belief, however achieved, in a mechanistic theory of life; and perhaps the criticism which will, in the end, invalidate Freud's arguments, may come, not from those who dispute the accuracy of his deductions, but from those who question the fundamental assumption on which all his reasoning rests—the assumption that all the phenomena of life and mind can be interpreted in terms of the physical sciences."[20]

Now no scientist with any appreciation of the real nature of science as a mere weapon for attacking and controlling our experience, and not as a unique road to the attainment of absolute knowledge, would contend that this is the only conceivable weapon, or that other weapons may not prove to be ultimately more effective. He may reasonably hold, however, that at present it is the only weapon which he feels he can trust, that the other methods hitherto proposed lead him into a sea of divergent speculations in which he can find no solid ground whereon to build with surety, and that he is at least justified in pushing the method of science to its limits in the field of psychology, before he consents to abandon a mode of attack which has succeeded in the past few centuries in giving us a control of our experience incomparably greater than anything before achieved.

Whether or no it will ultimately be shown that a psychology founded on the method of science is inadequate, it is at least desirable that we should know with certainty when we are employing that method and when we are going beyond it. The aim of the foregoing criticism of Freud's work has been to set out in broad lines the respects in which it satisfies the canons of scientific validity, and those in which it appears to fall short thereof. The reproach will rightly be levelled at this criticism that it attains to no certain point of acceptance and rejection, and it can only be pleaded in justification that this picture of benevolent scepticism portrays faithfully the stage in the road of conviction to which the mind of the writer has succeeded in travelling.

### THE SPHERES OF MEDICINE AND SCIENCE.

These various considerations lead us to a further point. The spheres of medicine and science are not quite the same, however much we may strive to identify them. On the one hand, medicine is partly an art, and on the other hand its essential goal is therapeutic result, and not the acquirement of pure knowledge. Therapeutics has a normative aim, and normative aims cannot be fitted squarely into the structure of positive science. Hence medicine cannot afford to submit itself entirely to the narrow and rigid limits of science, but must demand a greater degree of freedom. In therapeutics it is justifiable to act on hypotheses which lack full or perhaps any scientific validity. Medicine has always claimed this right in very liberal measure, and the principle must be applied to the sanctioning as therapeutic procedures of psycho-analysis and the many variants and derivatives of psycho-analysis, until our knowledge is commensurate with the task of giving or denying to them an assured place in our professional armoury.

Finally, a word may be said concerning the actual and potential relationships of psychopathology to the other avenues of attack which seek to penetrate the field of medicine. In the first lecture it was pointed out that, while psychology must insist upon the privilege of formulating its own concepts and extending these so far as they are found to be useful in the explanation of human life and behaviour, the possibility must always be kept in mind that these concepts may ultimately be capable of reduction to the wider concepts of some other branch of science. Just as the concepts of physiology may in the future be brought under the concepts of chemistry and physics, so may psychology be merged in a wider physiology and psychopathology in a wider pathology. This complete merging may never be practicable; portions of experience only to be dealt with by psychological conceptions may "stick out," however far we may ultimately succeed in thrusting the major part of the phenomena of psychology into a physiological or chemical framework. We have seen, for example, that "purpose," which seems to be an integral factor in psychology, appears to be inherently incapable of incorporation into the structure of mechanistic science.[21] Nevertheless, as each branch of science is justified in endeavouring to explain as much of our experience as it can, the aim of subsuming the concepts of one branch under the wider concepts of another branch is clearly a desirable one in the interests of the unification of knowledge. It will therefore be profitable to inquire how far such an aim has been achieved or shows prospects of being achieved so far as psychopathology is concerned.

[20] T. W. Mitchell: Brit. Jour. of Med. Psychol., 1923, p. 242.

We must confess that up to the present time but little solid progress in this direction can be reported, though innumerable attempts have been made to bring the problems of psychology and psychopathology under the conceptions of physiology. Most of these attempts have consisted, however, in the preliminary acceptance of a psychological conception and a subsequent free translation of its terms into hypothetical nerve forces and nerve units, a process which seems to give ineffable satisfaction to certain minds, but which adds little or nothing to our knowledge and understanding. Other attempts have led to the construction of anatomical and physiological concepts built entirely in the air, without basis or means of verification on the plane of objective facts, and therefore without scientific justification or utility. Nevertheless, something has been done, and vistas have been opened up along which prospects of considerable future progress may be discerned. One such vista has been offered by the development of endocrinology. It is not difficult to foresee a time in which the psychological conceptions of instinct and instinctive force may be partially reduced to the conceptions of biochemistry, and Freud has himself envisaged the possibility of certain of his concepts becoming ultimately capable of interpretation in biochemical terms. In the present state of our knowledge, however, all this does not take us very far beyond the realm of speculation. However desirable the merging of psychopathology in general pathology may be held to be, it must be admitted that the time for its consummation has not yet arrived, and that there is a field in which psychopathology can aid our understanding and our practice in a way not yet possible for physiopathology. So long as this holds it is more profitable, both for science and for medicine, that psychopathology should be allowed to march independently as best it can, rather than that general pathology should burst its legitimate bounds in a dubious attempt to incorporate phenomena with which it is at present unfitted to cope.

---

[21] Cf. Drever, Instinct in Man, second edition, 1921, p. 5. ". . . the psychologist finds in the psychical series important factors, which have, and can have, no analogue in the physical series, as, for example, conscious purpose. It may be argued, therefore, that psychology will always preserve biology from being swallowed up by physiology."

# BLOOD-SUGAR STUDIES IN ENCEPHALITIS LETHARGICA.

By P. K. McCOWAN, M.D. Edin., M.R.C.P. Lond., D.P.M.,

J. S. HARRIS, M.D. Edin., D.P.M.,

AND

S. A. MANN, B.Sc. Lond., F.I.C.

The following report presents some of the results obtained from a series of investigations that are being carried out in connexion with cases suffering from the certifiable sequelæ of encephalitis lethargica who have come under the care of the Mental Hospitals Committee of the London County Council. By special arrangement the majority of these cases are now admitted to West Park Mental Hospital.

The mental aspect of a series of such cases has been dealt with by one of us (P. K. McCowan),[1] and in this investigation the cases have been submitted to metabolic function tests—viz.: (1) the blood-sugar response to glucose ingestion; (2) the lævulose test for the glycogenetic function of the liver. The lævulose test for liver glycogenetic efficiency was considered worthy of investigation in view of the work of various observers—e.g., Ottonello,[2] and Runge and Hagemann,[3] indicating that inefficiency of liver function is a practically constant feature of post-encephalitic Parkinsonism, leading to the supposition that in the acute stages of the disease the liver is implicated just as it may be in any severe infection, and that in due course its function becomes a dysfunction. If this reputed liver dysfunction was actually present it might be expected that the lævulose test would show it, and incidentally point to hepatic insufficiency as a possible cause of the abnormal sugar curves obtained.

### *The Blood Curve in Encephalitis Lethargica.*

It has been shown that marked abnormalities of the blood-sugar curve following glucose ingestion may occur in mental disorders; also there is evidence that variations in the blood sugar curve may give indications of the progress of the case and also be a useful guide to therapy and treatment.[4] For these reasons the blood-sugar curve following the ingestion of 50 g. glucose has been investigated, and work on the variations produced by therapy, with especial reference to hyoscine treatment, is still in progress. The latter will be reported in a later note, but the types of blood curves found in 15 cases will be reported in this paper. The investigations were made on the morning following a 12 hours' fast, the patients being in bed and the room being kept at a temperature of about 65° F. The blood-sugar values were determined at fixed intervals up to two and a half hours after the ingestion of 50 g. glucose in 8 oz. of water. The blood-sugar estimates were made by the Calvert method.[5]

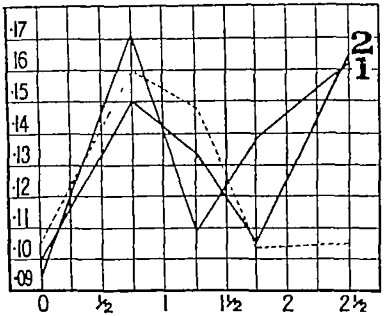
The normal blood curve is now well known, and it is sufficient to say that in the normal individual glucose ingestion is followed by a variable rise in blood-sugar (about 0·17 per cent. after 45 minutes), followed by rapid glycogenesis and a fall to the original fasting level within two hours of administration of the sugar meal. A sustained hyperglycæmia, according to MacLean,[6] indicates a defective storage mechanism and impaired glycogenetic function of the organism.

The factors concerned with the rise and the fall of the blood-sugar curve have been dealt with in detail,[4] and a summary may be helpful in the endeavour to appreciate the significance of the results obtained.

The rise of the blood-sugar curve depends on rate of absorption and glycogenolysis, and the fall on excretion, combustion, and storage (glycogenesis). The factors concerned with increased glycogenolysis and resultant hyperglycæmia are: (1) hyperthyroidism and increased secretion of the pars nervosa of the pituitary; (2) increased activity of the sympathetic system with hyperactivity of the suprarenal glands; (3) increased pH of the liver (Langfeldt [7]). The only known factor concerned with glycogenesis is the pancreas.

*Figs. 1 to 4 are Blood-sugar Curves following 50 g. Glucose; Encephalitis Lethargica. The dotted line shows the normal blood-sugar curve.*

FIG. 1.

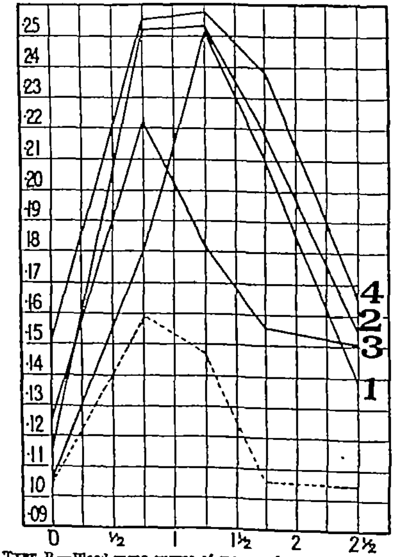


TYPE A.—Blood-sugar curve normal in shape, but followed by a secondary hyperglycæmia.

### *Types of Blood-Sugar Curves Obtained.*

Examination of the blood-sugar curves showed that they fell into three definite and distinct types. These, for the sake of clearness, have been named A, B, and C.

FIG. 2.



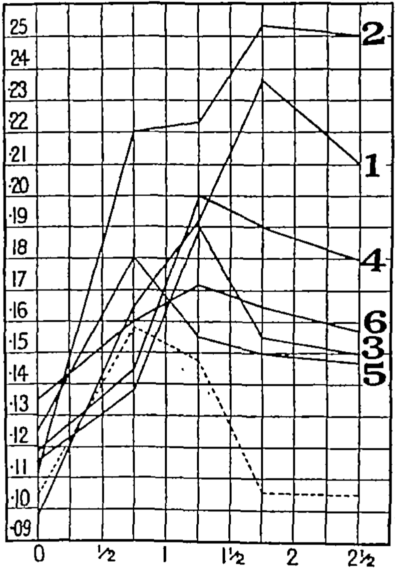
TYPE B.—Blood-sugar curves of more or less normal contour, but with high maximum blood-sugar values.

*Type A.*—Curves at first normal in shape, but followed by a secondary hyperglycæmia. The blood-sugar percentage reaches its maximum and falls to the fasting level in the normal length of time (about one and a half hours), but thereafter immediately rises to a considerable height. Two cases belong to this group. One shows Parkinsonism plus emotional facility (Fig. 1 (1) ), the other shows Parkinsonism plus apathy (Fig. 1 (2) ).

*Type B.*—Curves with a more or less normal contour but with high maximum levels (above 0·2 per cent.). The maximum levels of the curves in this group lie between 0·2 and 0·20 per cent., but each curve at the two and a half hour interval has almost regained the fasting level. There is no sustained hyperglycæmia. Four cases are found in this group and their mental and physical states are enumerated below: (1) Parkinsonism without undue apathy or depression (Fig. 2 (1) ); (2) Parkinsonism plus apathy (Fig. 2 (2) ); (3) Parkinsonism plus depression (Fig. 2 (3) ); (4) slight Parkinsonism plus mild depression (Fig. 2 (4) ).

*Type C.*—Curves showing sustained hyperglycæmia. Six cases belong to this group: (1) Mild Parkinsonism, with depression and persecutory delusions (Fig. 3 (1) ); (2) paralysis agitans plus agitated melancholia (Fig. 3 (2) ); a case included in the series on the hypothesis that paralysis agitans and encephalitis lethargica are the result of the same pathological condition; (3) Parkinsonism plus emotional facility (Fig. 3 (3) ); (4) Parkinsonism plus marked apathy (Fig. 3 (4) ); (5) no *Parkinsonism* but a "difficult" type (Fig. 3 (5) ); (6) no Parkinsonism but of "apache" type (Hall) plus epilepsy (Fig. 3 (6) ).

FIG. 3.



TYPE C.—Blood-sugar curves showing sustained hyperglycæmia.

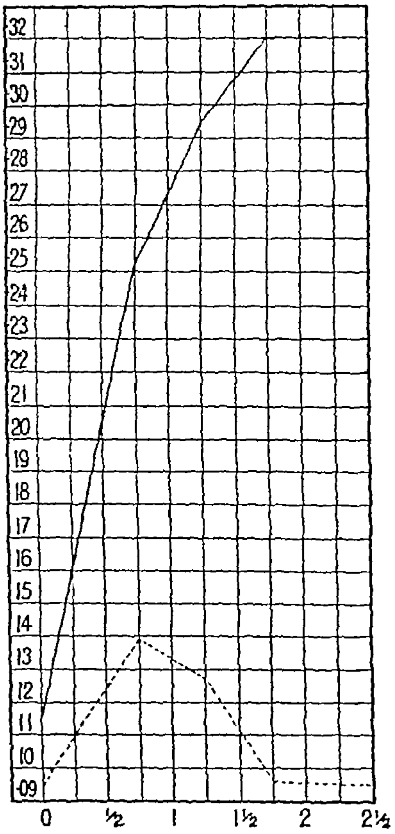
Two of these curves show very high maximum levels (Fig. 3 (1 and 2) ). Fig. 4 shows a curve which belongs to the C type, but, on account of its extreme maximum value, it was found necessary to place it *in a separate* diagram. The patient was in a stuporose condition and showed *numerous* physical *sequelæ* of encephalitis lethargica.

Two of the cases in this group (Type C) showed a slight glycosuria two hours after the ingestion of glucose. In no other of our cases was glycosuria found.

### *Discussion.*

Any attempt to interpret the abnormalities shown in the above-described types of curve cannot in the present state of our knowledge of carbohydrate metabolism be in any respect final, but one or two points seem to be worthy of consideration. In those curves depicted in Fig. 1 as belonging to Type A we have an appearance which resembles the normal blood-sugar curve. In the latter there is quite commonly a reactionary rise which, however, does not occur to such an extent as in this type of encephalitic curve. It is quite possible that this abnormally marked reactionary hyperglycæmia is due to a state of hyper-excitability in some part of the body mechanisms concerned with metabolism. In Type B (Fig. 2) the curves are all of the kind which one associates with a state of hyperthyroidism, but there was no clinical evidence of this disorder in the cases under review.

FIG. 4.



Blood-sugar curve showing high blood-sugar values and markedly sustained hyperglycæmia.

Type C is composed of curves which show sustained hyperglycæmia. This kind of curve is very commonly met with in other types of mental disorder. It will be noted that the curves that show the most markedly sustained hyperglycæmia with high maximum levels (Fig. 3 (1 and 2)) are found in cases whose mental state is one of melancholia. This agrees with the findings of Drury and Farren Ridge,[8] Mann,[4] and other observers, who have shown that the greatest interference with carbohydrate metabolism is found in patients who exhibit melancholia or stupor. That the latter mental state can be associated with great abnormality in carbohydrate metabolism is further proved by the case shown in Fig. 4. This patient was in a stuporous state when the blood-sugar curve was obtained, and she died some weeks later of encephalitis lethargica. This prolonged hyperglycæmia which is shown by the curves in this group is due to some interference with glycogenesis. It must be remembered, however, that blood-sugar curves showing sustained hyperglycæmia are obtained in infective conditions quite unassociated with mental abnormalities. Thus Olmsted and Gay[9] show sustained curves in a number of cases of focal infection. Pemberton and Foster,[10] investigating chronic arthritis, obtained curves showing sustained hyperglycæmia in severe cases, but normal curves were obtained following removal of the septic focus (teeth or tonsils).

Stavely Dick [11] reports hyperglycæmia and high and prolonged blood-sugar curves following glucose administration, after vaccine injection in non-diabetic cases. He would explain this as a defensive hyperglycæmia, but Allen,[12] in his comments on these results, regards them as due to toxic depression of pancreatic function. In this connexion it is of interest to mention that Rosenthal [13] showed that the injection of diphtheria toxin prevented glycogen formation.

It has been suggested by one of us [1] from a cli
study of the cases of this series that encepha

hydrate ingestion. The blood-sugar determina
were made by the Calvert method.[6] The re
obtained are given in the table.

The lævulose test is based on the experim
findings of Sachs [15] and F. C. Mann and Maga

that probably the liver alone is concerned with glycogenesis following lævulose ingestion. It was generally accepted that the normal individual gave no appreciable blood-sugar rise following a lævulose meal, whereas cases of hepatic disease showed disturbance of the glycogenetic function and a rise of blood-sugar resulted. The variations in the normal response have been investigated by one of us (S. A. Mann[17]) and by Tallermann,[18] and it is evident that an appreciable blood-sugar rise can occur in the normal individual.

The interpretation of these results presents a certain degree of difficulty, for observers are by no means unanimous as to what should constitute a positive result; that is, what is to be looked upon as definitely indicating the presence of hepatic insufficiency. Beaumont and Dodds[19] consider that if the blood-sugar level exceeds 0 14 per cent., or if a rise of 30 mg above the fasting level occurs after 40 g lævulose, then the reaction may be accepted as positive De Wesselow,[20] on the other hand, states that if a hyperglycæmia of 0 18 per cent. occurs and persists for more than two hours after the lævulose ingestion it can safely be concluded that there is some hepatic dysfunction present. According to Beaumont and Dodds's criteria four cases (B D., V C, C. D 1, J C 1) show positive results; according to De Wesselow one case (J C 1) is definitely positive. From the examination of normal cases and a large number of mental cases,[17] however, it would seem that a positive reaction should be considered not so much in relation to the blood-sugar level attained, but more with regard to the persistence of hyperglycæmia two hours or longer after the lævulose ingestion. It is the general contour of the curve which is important In the normal person the blood-sugar level after a lævulose meal has returned to the fasting level by the end of two to two and a quarter hours, and any definite tendency on the part of the curve to remain elevated to an appreciable extent after this period of time should be considered as denoting the presence of hepatic insufficiency Judged from this standpoint three cases (B D., J C 1, S H. 1) show positive reactions It will be noted that certain of the cases (C D, J C, S H.) which gave results which might be considered as indicating a positive reaction according to one or more of the various criteria were given a second meal of lævulose after an interval of seven days, when all of them gave strictly normal curves This would seem to indicate, if reliance is to be placed on the lævulose test, that the liver insufficiency in these cases was of a purely temporary nature.

It can therefore be concluded that, although certain observers maintain that there is hepatic inadequacy in encephalitis lethargica, this is not borne out by the results of the lævulose test It must be remembered, however, that the value of this test in demonstrating slight degrees of hepatic derangement is somewhat problematical.

### *Blood Sugar Fasting Levels in Encephalitis Lethargica.*

It is held by some investigators that an increase of sugar in the cerebro-spinal fluid is diagnostic of post-encephalitic conditions. Our work agrees with that of Halliday[21] in controverting this opinion Goodwin and Shelley[22] have found a constant ratio between the fasting blood-sugar level and the spinal fluid sugar (60 per cent.) In view of this finding, the fasting blood-sugar levels of the present series support the conclusions of Halliday that there is no characteristic increase of the sugar in the C-S.F in fasting post-encephalitic patients An increased blood-sugar and spinal fluid value may occur in this condition, but is by no means characteristic of it, and no diagnostic value can be placed in such findings

### *Conclusions*

1. In post-encephalitis lethargica there is definite derangement of carbohydrate metabolism as shown by the blood-sugar curves. 2 The lævulose test does not support the contention that there is definite permanent hepatic insufficiency in post-encephalitis lethargica 3 The majority of post-encephalitis lethargicas show a hyperglycæmia following glucose ingestion, markedly sustained in 50 per cent of cases. 4. The mental states of depression and stupor were associated with the most pronounced abnormalities of carbohydrate metabolism. 5 No correlation could be found between the clinical pictures and the types of blood-sugar curves obtained. 6 Although no diagnostic value can be placed on blood-sugar curves in post-encephalitis lethargica, the fact that the only normal curve was obtained in a patient who had recovered from his psychosis suggests that prognostic significance may be attached to them. 7. The hyperglycæmia found in all the cases is quite in keeping with the suggestion that encephalitis lethargica is of the nature of a toxæmia, usually acute in onset, but becoming chronic in nature

In conclusion, we would express our indebtedness to Dr Golla, director of the Central Pathological Laboratory, Maudsley Hospital, for his unfailing interest and guidance, and to Dr. Roberts, medical superintendent, West Park Mental Hospital, for permission to publish details of cases

# THE STEAM CAUTERY

BY H. S. SOUTTAR, C.B E, F.R.C.S. ENG,
SURGEON, LONDON HOSPITAL.

THE destruction of malignant tumours by heat is probably one of the most ancient forms of surgery, but with the introduction of methods of direct removal the actual cautery fell into disuse. Yet there are many malignant growths whose removal by direct surgery is difficult or impossible, and for these heat has again been invoked, by the use of the diathermy current. Over the actual cautery this possesses the advantage of deep penetration, whilst, instead of being rapidly burnt away, the tissues are coagulated. The slow separation of the slough allows time for granulations to form, so that the tumour is converted into a foreign body and is cast off by natural processes.

Precisely the same result may be obtained in a much simpler manner by the slow penetration of heat from a cautery maintained at a low temperature, and this is very conveniently done by a current of dry steam. For the past two years I have been using an instrument of my own device founded on this principle, and the results have exceeded my expectations. It is constructed as follows. (See figure)

Steam is generated in a small boiler (A), solid "meta fuel" being conveniently used as a source of heat The steam is superheated by being carried directly through the flame, and it then passes along a thick rubber tube (B) to an insulated handle (C). This terminates in a nozzle on to which applicators of various forms (D, a, b, c, d, and e) can be screwed, and the steam, after entering the applicator, returns by the handle to the discharge tube. It will thus be seen that the applicator is maintained constantly at a temperature closely approximating to 100° Centigrade

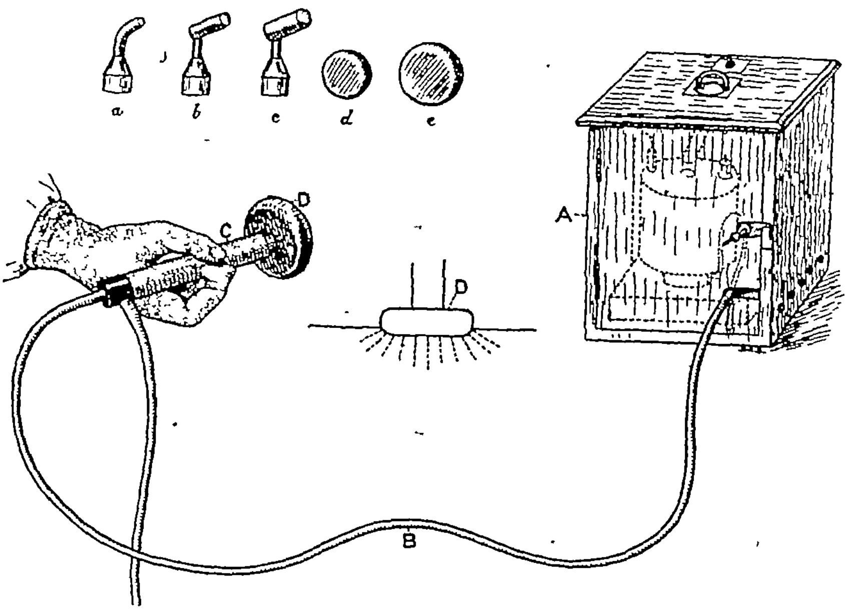
The applicators vary in size from small points up to metal discs 3 inches or more in diameter.

### *Method of Application.*

So long as the applicator is kept in contact with the tissues heat slowly penetrates and produces coagulation, the depth of penetration for any one applicator being simply a function of the time and of the permeability of the tissues. With the large applicators and on moist tissues penetration takes place at the rate of about 1 inch in ten minutes. This can be easily demonstrated upon a piece of beef-steak, and a section will show at once the complete coagulation which results, an exceedingly tough coagulum being formed.

Though this method resembles diathermy, it differs in important details. In contrast to diathermy very large applicators may be used, the rate of penetration being slightly greater with large applicators than with small ones. With large applicators it is an exceedingly powerful machine, and I venture to think that it is the most potent appliance we at present possess for dealing with large masses of inoperable growth. The rate at which great masses of fungating carcinoma coagulate and disintegrate before it is astonishing, and yet in the end dense coagulum is left which gives ample protection to the deep tissues and allows time for their recovery, for the closure of large vessels, and for the formation of granulation tissue.

Although the instrument was originally devised for dealing with large inoperable growths, it has been found in practice to be applicable to a number of other conditions. The depth of penetration is uniform over the surface of application and is under perfect control, so that small superficial growths and ulcers can be treated with certainty and yet without risk to the underlying deep structures.



The method has been found of peculiar value in the treatment of epithelioma of the skin, especially where this arises on a scarred surface, as after the treatment of lupus and similar conditions by X rays. We have, unfortunately, seen a large number of these cases, and they sometimes present a surgical problem of great difficulty. Excision leaves a widely gaping wound, which heals but slowly owing to the underlying fibrosis and the endarteritis which the rays have caused. Suture of the margins is useless, and grafts take but poorly. We have found that destruction of the growth by the steam cautery, easily carried out under local anæsthesia, leaves a much smaller wound, protected by a tough coagulum. When this separates a granular surface will be found on which a graft takes readily.

### *Illustrative Cases.*

The following cases illustrate a few of the applications of the method.

CASE 1.—A. B., a man aged 53. For 33 years he had suffered from lupus which had extended over practically the whole of his face and neck, and the whole of this area was now covered by the scars of healed lupus. He had been treated with Finsen light at the London Hospital and with X rays elsewhere. For five years a nodular growth had been gradually spreading above the left angle of the mouth. A small part of the nodule was excised and the remainder and the whole of the base treated with the steam cautery. Sections showed it to be a squamous carcinoma. The cauterised area healed rapidly and after nine months it cannot be distinguished from the rest of the surface. There is no trace of recurrence.

CASE 2.—C. D., a man aged 40. Ten years ago he had prolonged treatment with X rays for sycosis barbæ, and the whole of the beard area was covered by scar tissue. For a few months an ulcer had been spreading in the left malar region; it was now about 1 inch in diameter, and had all the characteristics of an epithelioma. It was treated by the steam cautery and four weeks later a Thiersch graft was applied. The graft took at once. Six weeks later, though still perfectly healed, the appearances suggested a recurrence of growth below the graft. For safety's sake the graft and the tissue beneath it were excised. The section showed nothing at all but fibrous tissue covered by epithelium. The small wound left healed rapidly.

CASE 3.—E. F., a man aged 47. Twenty years ago lupus began on the left side of his face and spread until the whole of the cheek and the left side of the neck were involved. It was treated with X rays and this area was converted into scar-tissue. For two and a half years a warty out-growth on the scar had steadily increased in size, until it now formed a huge fungating mass extending from the nose to the mastoid process and down into the neck. The whole of the growth was removed with the steam cautery and six weeks later it was found possible to graft three-quarters of the area, the grafts taking well on sound granulation tissue. The growth, however, spread further down the neck and involved the vessels, so that in spite of the local success further treatment of the case had to be given up as hopeless.

CASE 4.—G. H., a woman aged 24. For a year she had suffered from hyperthyroidism with tachycardia and slight enlargement of the thyroid. She had been treated on several occasions with X rays, but after one of these she noticed a severe erythema of the epigastrium. The treatment was discontinued for a time, but on its resumption the erythema recurred, the skin broke down, and a deep ulcer formed. It was then found that the shield of the X ray tube was defective. In the epigastrium there was an ulcer 3 inches in diameter and extending deeply into the tissues; the recti muscles themselves were exposed. It was thought that such an ulcer was almost sure to become malignant, but as it was grossly septic, and as its effective excision must at least reach the peritoneum, it presented a very difficult problem. By means of the largest applicator of the steam cautery the whole ulcer was dried up and rendered sterile, and this huge sterile coagulum was then excised. On freeing the deep tissues and undercutting the skin it was found possible to close the wound and it healed by first intention, leaving only a median scar.

CASE 5.—J. K., a man aged 21. A year previously he had been thrown from a motor-bicycle and his face badly scored. The right side of the face and the left side of the nose were covered by deep scores rendered very noticeable by the fact that they contained pigment, probably tar, situated in the dermis. Excision of such extensive scarred areas was out of the question. With a small point attached to the steam cautery each scar was carefully coagulated so that the actual points of pigment sloughed out. The result was extraordinarily good, the resulting white scars being scarcely noticeable.

### *Wide Range of Utility.*

It will be seen that the steam cautery has a wide range of utility. With large applicators it can be used as an instrument of great power for the destruction of large masses of malignant growth. With small points it can be used in the most delicate manipulations of facial surgery. It has probably many applications in the treatment of pathological conditions of the skin and the accessible mucous membrane, and under certain circumstances its powers of sterilisation can eliminate gross sepsis and greatly simplify surgery. It appears to be capable of accomplishing all that can be done by diathermy, with greater facility, with less risk, and at a minute fraction of the cost.

The instrument was produced in my experimental laboratory at the London Hospital. It can now be obtained from Messrs. Allen and Hanburys.

# ELECTROCARDIOGRAPHIC CHANGES IN RHEUMATIC CARDITIS.

BY C. W. CURTIS BAIN, M.B. OXF., M.R.C.P. LOND.,
MEDICAL OFFICER TO OUT-PATIENTS, HARROGATE INFIRMARY
AND
C. K. HAMILTON, M.B. OXF., M.R.C.P. LOND.,
JOHN AND TEMPLE RESEARCH FELLOW, ST. THOMAS'S HOSPITAL.

THE modifications of cardiac rhythm in acute rheumatism were investigated by Parkinson, Gunsen, and Gosse,[1] who found some alteration in 30 per cent. of cases. Recently, Cohen and Swift,[2] working on the same lines, noted heart-block, flutter, and fibrillation during the acute attack. Both these investigations were limited to the time in which the patient remained in bed, and in nearly every instance acute articular rheumatism was present at the time of investigation.

In children it is well known that the rheumatic infection may take different forms. There may be no acute onset with pyrexia, the joints may not be affected at all, but the infection may reveal itself by the appearance of subcutaneous nodules, by the involvement of the central nervous system, giving rise to chorea, or be disclosed by a history of migratory limb pains, more or less severe, which may be accompanied by anæmia, tonsillitis, listlessness, and loss of weight, &c. In any of these forms there is a special tendency for the heart to be attacked, so that a child may be brought up for the first time on account of limb pains and loss of flesh, and be found to have an apex-beat outside the nipple line and a developed mitral lesion. This condition has been described as rheumatic carditis. Although well recognised clinically, there are as yet few observations controlled by the electrocardiograph on children with this affection who were not sufficiently ill to be confined to bed. We have, therefore, observed a series of 50 children attending a special rheumatic out-patient clinic. The clinic consisted of about 400 patients, of whom 40 per cent. had cardiac lesions. Those utilised were not specially selected; their ages varied between 4 and 13 years.

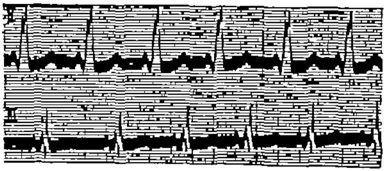
The patients were examined by two observers independently, and the physical signs compared. The size of the heart was determined by taking the apex-beat as the left border, and dullness to percussion for the right border. When any doubt arose the findings were checked by X ray examination. In grouping the cases according to valve lesions the following method was adopted. A few cases with heart enlargement were found to have no murmur, or a systolic which was localised to the apex. These were termed myocardial on the assumption that any incompetence of the mitral valve was due to the enlargement of the left ventricle rather than to disease of the valve. Mitral disease was assumed to be present when the systolic murmur was well conducted. Any diastolic or presystolic murmur at the apex was taken to denote the presence of mitral stenosis. The last group consisted of those in whom aortic regurgitation was present in addition to the mitral lesion. To these were added two cases who presented the physical signs of adherent pericardium.

### *Summary of Cases.*

The following abnormalities were found:—

1. Evidence of impaired conduction from auricle to ventricle through a lengthening of the P.R. interval to over 0·2 of a second was noted in two cases. In both there was an established mitral lesion. This is known to be associated with heart-block in the adult, and is probably due to an extension of the fibrosing process from the base of the valve down to the A.V. conducting system.

2. Impaired intraventricular conduction "arborisation block," as shown by a widening of the Q.R.S. complex with notching of the R wave, was noted in one case (see figure). This patient had a P.R. interval of 0·08 second, or half the average interval found in the series. It is probable, however, that the impulse arose normally in the sino-auricular node, and that the remainder of the P.R. interval was lost in the widened Q.R.S. He had no valve lesion, but the heart was enlarged.



Leads II. and III. showing a P.R. interval of 0·08 sec., a notched and widened Q.R.S. complex, and an early depression of the T wave.

3. Inversion of the T wave in leads II. and III. was present in two cases. One at the age of 12 had a double valve lesion, and had already been in the hospital for cardiac failure. The other had a large heart without valve lesion. Inversion of T in lead III. only occurred in a further six cases, but was not taken as evidence of myocardial disease.

4. A depression of the S.T. interval followed by a small T occurred in three cases. This took the same form as that caused by digitalis. No digitalis, however, had been given. One child died three months after examination. Another had an adherent pericardium and a very large heart. The third, who does not show it so characteristically, has already been described for abnormalities with the Q.R.S. complex.

5. Extrasystoles were found once only. They were auricular in origin; were frequent, and had been noted for over a year. The patient had a large heart without a valve lesion.

6. Sinus arrhythmia of a slight grade was commonly present when the rate was slow. The child in whom it was most marked had an advanced carditis with a large heart and mitral incompetence.

7. Predominating hypertrophy of either ventricle. Although several cases of aortic disease were examined, in one only was there any sign of a left ventricular preponderance, and in that the S wave measured 7 mm. A right-sided preponderance was found in two cases. In one at the first examination the

*Remarks.*—CASE 42. Died with pericarditis three months later. CASE 44. Between examinations had been in ward with subacute attack with pericarditis. CASE 49. Recurrent pericarditis during four years. Broadbent's sign positive. CASE 50. Broadbent's sign positive.

heart was not greatly enlarged, and there were signs of mitral regurgitation with some stenosis. Three months later the apex was 2½ inches further out, and the stenosis had progressed considerably. In another month and a half the apex had receded 1 inch, but was now formed entirely by the right ventricle; there was no evidence of mitral regurgitation—merely an advanced stenosis. The other, in whom the preponderance was less, had on the first examination no evidence of valvular disease; six weeks later she had signs of an early stenosis.

*Discussion.*

Pathologically, as Poynton and Paine [3] pointed out, the essential characteristic of rheumatic carditis is the Aschoff body. These inflammatory nodules can always be found microscopically in the myocardium, usually in the neighbourhood of the arterioles. They have a tendency to clear up, and indeed, at no time seem to exercise much effect on the function of the heart. Carey Coombs [4] notes that though they are found in numbers in the septum, yet heart-block in children is rare. He therefore postulates some toxic action on the metabolism of the muscle cells to account for the heart failure during the acute attack. In most cases the muscle recovers from this toxic action, and the patient has to face the risk of reinfection, and to meet the effects of the invasion on the valves which do not recover in the way the muscle does, owing probably to the poverty of their blood-supply.

Such a toxic action affecting the whole of the cardiac musculature could not be expected to influence the electrocardiographic curve, and one such case taken on the day of admission, four days before his death, showed a normal curve, with the exception of a tachycardia. It seemed, however, probable that recovery would often be incomplete, and that after the acute carditis had subsided the electrocardiograph might be able to differentiate between those cases in which, excluding the reinfection risk, the valve lesion was the only factor to be considered, and those in which an abnormality in the curve denoted some additional myocardial damage. In this series eight gave evidence of myocardial disease, so that out of the whole clinic 16 per cent. of the heart cases, or 6 per cent. of the total cases of rheumatism, were affected. The risk of reinfection cannot be assessed. Moreover, one child who was taken before and after a subacute attack with pericarditis, during which he had been in hospital, showed no alteration in the curve, although clinically he was in a considerably worse condition.

For the remainder of the cases the prognosis is dependent upon the valvular lesion. The dilatation and hypertrophy which take place during the active carditis stage appear not to be due to any valve lesion; they affect each ventricle and do not influence the electrocardiographic curve. When the myocardium is not permanently damaged this enlargement subsides to the point at which it is necessary to compensate for whatever valve lesions there may be. This compensatory hypertrophy was not sufficient in 94 per cent. of cases to cause one ventricle to preponderate over the other. One child with aortic disease showed a small amount of left-sided preponderance. Two with mitral disease showed a right-sided preponderance. In one case, in which the preponderance was great, the stenosis progressed rapidly.

*Summary.*

(a) Fifty children with evidence of active rheumatic carditis have been examined electrocardiographically. (b) Lengthening of the auriculo-ventricular conduction time was present in two cases. Impaired intraventricular conduction was present in one. (c) Abnormalities in the T wave in leads II. and III. occurred in five cases. (d) Extra-auricular systoles occurred in one. (e) Preponderance of one ventricle over the other was unusual; a right-sided preponderance appeared to have a bad prognosis.

We must express our thanks to Dr. M. A. Cassidy for placing his department at our disposal, and to Dr. R. C. Jewesbury for permission to use the clinical material.

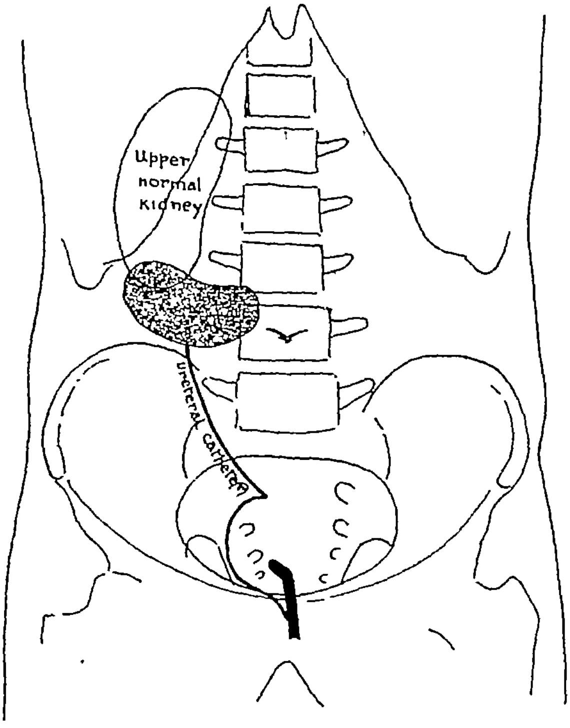
# Clinical and Laboratory Notes.

## A CASE OF
## CROSSED DYSTOPIA OF THE KIDNEY.

BY ALWYNE J. COMPTON, F.R.C.S. ENG.,
SURGEON TO THE GERMAN HOSPITAL, DALSTON.

DURING the course of a laparotomy the following abnormality in the position of the kidneys was found.

L. H., male, aged 52 years. One kidney, normal in size, shape, and position, was found on the right side. A second kidney, about 3 in. long and 2 in. broad, lay obliquely, at a lower level and in front of the lower pole of the normal kidney; its hilum directed upwards and slightly to the left, its surfaces facing anteriorly and posteriorly, its long axis occupying the middle part of a line joining the umbilicus and the lowest part of the right tenth costal cartilage. The inner and somewhat lower pole reached to within an inch of the middle line, in front of the inferior vena cava. The convex margin of the kidney lay in the umbilical plane, and the outer and upper pole overlapped the lower pole of the normal kidney by about one inch. Both kidneys lay in the retro-peritoneal tissue, completely separate from each other, and neither of them showed abnormal mobility. There was nothing unusual about the stomach, duodenum, or colon. Owing to a considerable deposit of fat, neither the ureters nor the renal vessels could be made out definitely. No trace of any kidney could be found in the left loin or elsewhere on the left side.



No kidney shadow on the left side. Course of ureter shown as a thick line leading from the cystoscope to the lower of the two right-sided kidneys. The normal kidney is outlined, the lower one stippled.

*Cystoscopic Examination.*—The urethra was normal, also the mucous lining of the bladder. The latter was of normal capacity. A prolonged search revealed only one ureteric orifice on the right side. The right end of the plica ureterica was prominent and smooth and formed two well-marked folds, one above and the other below the ureteric opening. An opaque catheter was passed into the ureter and ran up without a hitch as far as the lower kidney. A skiagram was taken with the cystoscope and catheter in place and is shown in the accompanying tracing. On the left side the plica ureterica was ill-defined, and no ureteric opening could be found. A shallow pocket, which looked as if it might be the opening, contained a little calcareous material, easily dislodged with the end of the catheter. The pocket was less than a quarter of an inch deep, and no jets could be seen coming out of it.

Apart from gall-stones, on account of which the operation was done, no other abnormality was discovered when the patient was examined.

## TWO CASES OF
## LESION OF THE PONS VAROLII OCCURRING UNDER GENERAL ANÆSTHESIA.

BY W. J. MCCARDIE, M.B., B.CH. CAMB.,
CONSULTING ANÆSTHETIST, GENERAL HOSPITAL, BIRMINGHAM;
AND
H. W. FEATHERSTONE, M.D., B.CH. CAMB.,
HONORARY ANÆSTHETIST TO THE HOSPITAL.

BY a coincidence the two patients, whose cases are here recorded, died within an hour of one another. They had been anæsthetised in the same theatre, and the symptoms presented by each patient, though of rare ocurrence, strongly resembled those of the other. As ether from the same batch had been employed, it was at first subjected to criticism, but the post-mortem findings, coupled with the absence of bad symptoms in other patients, have, we think, exonerated the ether.

### *The First Case.*

*Thrombosis of the Basilar Arteries during an Operation for Advanced Carcinoma of the Breast.* (By Dr. McCardie).—A woman, aged 60, suffering from cancer of the breast, was brought to the anæsthetic room at the General Hospital on Sept. 30th, 1925, for operation, at which the breast and axillary contents, which included one or two enlarged glands, were removed by Mr. Leonard Gamgee. Examination previous to operation had shown no evidence of secondary deposits. The patient was rather fat, but appeared to be in fair condition, and nothing specially abnormal was found in the lungs or the heart, except that the cardiac impulse was rather weak. The urine did not contain casts, blood, or tubercle bacilli, but there was a little pus. She said she had nasal obstruction, also a cold and an occasional cough. 1/100 gr. atropine was injected half an hour before operation, but no other drugs were given. $E_2C_1$ mixture of chloroform and ether, aided by a little ethyl chloride, was administered on an open mask, and induction being quiet and particularly rapid, anæsthesia was maintained throughout by the $E_2C_1$ mixture.

Her condition was quite good for about 25 minutes; anæsthesia was then fairly deep, the eyelids being half open and the corneal reflex nearly absent, but the pupils were fully contracted. At this point respiration, which had always been very quiet, stopped rather suddenly, although the pulse remained of fair quality and the colour good. Her tongue was pulled out and her chest was compressed a few times, the colour changed a little for the worse for a minute or so, and then respiration quickly reappeared. The operation was not interrupted. Her pupils still remained very small. The operation was finished and the patient sent back to bed apparently in fair condition. Nevertheless, she did not recover consciousness, but remained in coma. Gradually her breathing became stertorous, and her pupils pin-point in size. The coma deepened and death occurred 20 hours after completion of the operation. The temperature, which was 98·6° F. in the evening, gradually rose to 106° just before death. At the time of the operation I ascribed the unusual symptoms to toxæmia, probably of cancerous origin.

At the *post-mortem examination*, performed by Prof. Haswell Wilson, the following notes were made: Pathological summary: Carcinoma of the breast; generalised dissemination; cerebral softening. Heart: 350 g. Extreme degree fatty infiltration, especially on the right side. Slight atheroma of the coronary arteries. Lungs: Atrophied. Hilum and lower lobe of right lung showed large mass of tumour growth, which had eroded the pulmonary vein in one place. There was a mass of mediastinal glands infiltrated by tumour growth. Liver: 1300 g. Fatty degeneration and infiltration. Numerous small metastases throughout substance and on surface. Gall-bladder: A necrotic mass resembling tumour growth was found at the tip. Kidneys: Pale and fatty. Spleen: Atrophied and fibrous. Suprarenals: The left showed metastases of growth with hæmorrhage. Small nodule in right organ. Mesenteric glands:

They were hard and were infiltrated with tumour growth resulting in thrombosis of some vessels in the mesentery. Stomach: Several fungating metastases of tumour growth were discovered on opening the stomach along the lesser curvature. Brain: Thrombosis of the basilar arteries and of the Sylvian arteries. Multiple metastases in the cortex. Several old root softenings were found. A more recent hæmorrhage was discovered in the right half of the cerebellum.

The case, then, was one of acute dissemination of very widely spread cancer. Such patients are toxic, and stop breathing very easily. The arterial thrombosis would explain the coma, stertor, and pin-point pupils. It is difficult to prove when exactly thrombosis commenced, but, judging from the size of the pupils, it appears likely that the pons was injured shortly before respiration ceased temporarily. It is possible that the slowing of the circulation from exhaustion led to the clotting of blood, which initiated the chain of events leading to the fatal issue.

### *The Second Case.*

Instances of restoration of the heart-beat by direct cardiac massage, in patients who have collapsed when under the influence of chloroform, are by no means rare. Unfortunately, death usually follows a few hours later, and the case to which I draw attention is not an exception to this rule. Nevertheless, in several respects, this is an unusual case from which useful inferences may be drawn.

*An Unusual Case of Temporary Recovery of Respiration and Heart-beat in a Patient who apparently had Died under Anæsthesia, with a Fatal Sequel due to Associated Pontine Injury.* (By Dr. Featherstone.)—The patient, J. H., a well-developed man of 48 years, had suffered from indigestion for three weeks. On Sept. 30th, 1925, at 9.30 P.M., a duodenal ulcer perforated and the doctor who was summoned sent the patient to the Birmingham General Hospital without administering any opium or morphia. Laparotomy was performed at 5.35 A.M. by Mr. W. S. Adams, the resident surgical officer, to whom I am indebted for the notes of the operation. Thus there was an interval of about eight hours between the perforation of the ulcer and the operation.

When anæsthesia was commenced by one of the house surgeons the patient's general condition was quite good, although he was much distressed by the pain, and the abdomen was rigid. A chloroform-ether mixture, $E_2O_1$ preceded by atropine 1/100 gr. and no other drug, was employed for induction, and the patient struggled vigorously for nearly four minutes. Anæsthesia was continued with ether by the open method, but, although respiration was unobstructed and oxygen was given, the colour was inclined to be cyanotic. There was a small amount of mucous secretion. The surgeon found a pin-hole perforation of the duodenum, close to the pylorus, with free fluid and some flakes of lymph. As the pulse was weak and the anæsthetist was not satisfied with the man's condition, the surgeon contented himself with suturing the perforation without performing a gastroenterostomy.

After anæsthesia had lasted for about 20 minutes, while the surgeon was completing the duodenal suture, the colour improved considerably. There was only a light degree of anæsthesia. Tubes were inserted to the pelvis through a suprapubic stab, and to the right kidney pouch. The peritoneum had been sutured halfway along when the respiration became jerky. Anæsthesia was still light and the peritoneal suture was completed, and four deep silk-worm gut sutures were inserted. At this point the patient ceased to breathe. The colour was pink, although the pulse could not be felt at the wrist. Compression of the chest showed that the air-way was clear, and, while artificial respiration was continued, the wound was reopened. No cardiac impulse could be felt through the diaphragm. Cardiac massage, both through the diaphragm and afterwards by fingers inserted directly into the pericardium, did not elicit any response.

Two or three minutes after the heart had stopped 1 c.cm. of adrenalin was injected into the right ventricle without effect. Artificial respiration and cardiac massage were continued for three or four minutes, and then a second injection of 1 c.cm. of adrenalin was made as before. About 10–15 seconds after the second injection the heart commenced to beat. The impulses were weak at first, but after about ten systoles the contractions were of good force and the tone of the heart muscle was firm. Thus the heart had stopped for nearly ten minutes. Artificial respiration was continued without effect until a big stertorous inspiration occurred one hour after the heart had re-started. In the next ten minutes the patient took about a dozen voluntary breaths, and then breaths came at gradually diminishing intervals, until normal respiration was established about 20 minutes after the first voluntary response. The abdomen was closed by "through-and-through" sutures. During the state of apnœa the pulse-rate was 120 per minute, the pupils were half dilated, and the corneal reflex was absent. After the return of voluntary respiration the pupils gradually contracted until the patient left the theatre, but they were not at that time "pin-point." On the patient's return to the ward at 7.50 A.M., continuous rectal salines, the foot of the bed on chairs, and other restorative measures were instituted.

I saw the patient at 10.15 A.M., at the request of a surgical colleague, who suggested, as a first impression, that the condition of the patient resembled morphine poisoning. At that time both pupils were "pin-point," and there was a divergent squint, the left pupil being turned to the left. The breathing was stertorous, 36 per minute. The pulse was vigorous, 112 per minute, and the blood pressure reading was: systolic 160 mm., diastolic 75 mm. There was general muscular rigidity and hyper-excitability. Both knee-jerks were absent. The temperature was rising —viz., at 9 A.M. = 100° F.; at 10 A.M. = 102°; and (to anticipate) at noon = 103·4°; and at 1 P.M. = 101·1° (compare Dr. McCardie's case).

It was ascertained that no morphia had been given, and in view of the pin-point pupils, the stertorous breathing, the high blood pressure, and the rising body temperature, a diagnosis of hæmorrhage in the neighbourhood of the pons varolii was made. So striking were the symptoms that several surgical and medical members of the staff were asked to see the case and general agreement with this opinion was expressed. Furthermore, it appeared possible that the hæmorrhage had taken place as the result of the prolonged struggling during induction of anæsthesia. One of the physicians to the hospital tentatively put forward the suggestion that thrombosis during the arrest of the heart might have led to a small embolism in the pons, followed by extravasation of blood from the damaged vessels. The patient died at 1.45 P.M., about five and a half hours after restoration of respiration.

At the *post mortem examination*, performed by Prof. Wilson, the brain was found to be œdematous, and there was extreme congestion of the vessels in the region of the pons, especially round the floor of the Sylvian aqueduct; but there was no sign of embolism or hæmorrhage. The other organs were healthy, with the exception of the duodenal ulcers and general congestion of all the viscera. It was considered that the appearance of the pons varolii was compatible with the symptoms observed and with the fatal issue, but that histologically it would not be possible to demonstrate gross damage to the nervous tissues owing to the post-mortem changes in the 21-hour interval between death and autopsy.

The following points appear to be of special interest: (1) The cessation of heart-beat and respiration in a patient of fair general condition while under open-ether anæsthesia. (2) The restoration of the heart-beat by direct cardiac massage, with intracardiac adrenalin as an important factor. (3) The return of respiration after apnœa which had persisted for not less than 75 minutes. (4) The patient's general resemblance to a case of cerebral hæmorrhage or fracture of the skull, such as one is accustomed to see in the accident wards. (5) It may be concluded, with some justification, that stoppage of the circulation in the brain for ten minutes had led to irreparable damage to the pons and medulla. If we accept this as the explanation of the fatal issue which is so frequently the early sequel in cases of restoration of the heart-beat by cardiac massage, we shall be emboldened, when we find the heart has ceased to beat during anæsthesia, to undertake cardiac massage without any delay.

We have to thank Mr. Leonard Gamgee and Mr. Seymour Barling, the surgeons in charge of these cases, for their kind permission to record them.

---

HOSPITALS AND MOTOR ACCIDENTS.—It was stated at the annual meeting of Leeds General Infirmary that last year 768 victims of motor accidents were treated, and that, although the lives of many of these patients were saved, their contributions were "exceedingly small." Much the same story is told in the annual report of the Victoria Infirmary, Newcastle-upon-Tyne. There 595 injured persons were treated, of whom nearly one-half were retained as in-patients.

### SECTION OF SURGERY.

At a meeting of this Section held on March 26th Mr. R. C. B. Maunsell, the President, took the chair, and Dr. Maurice Hayes opened a discussion on

*The X Ray Treatment of Exophthalmic Goitre.*

He reviewed the results of radiotherapy in 100 cases of Graves's disease (90 females and 10 males) treated by him during the last 15 years. Sixty-two patients who completed the course of treatment were cured and able to follow their usual occupations. Fourteen were improved; they comprised eight who left off treatment before they were finally discharged, and six who were still under treatment. Sixteen abandoned treatment for various occupational reasons. The ultimate results of eight cases were unknown. There was recurrence in two cases; in one of them it followed encephalitis lethargica, and in the other it followed influenza. Four of the patients in the series had had previous operation. Three underwent operation shortly after the commencement of X ray treatment; one of these died, and another had a toxic adenoma. X ray treatment was given daily or on alternate days for a period of three weeks. After a month's interval this was repeated. Two or three series of applications were usually sufficient.

Dr. Hayes remarked that statistics of the surgical treatment of exophthalmic goitre were copious and reliable, whilst those of treatment by radiation were as yet incomplete; but a comparison of the results indicated that X ray treatment would probably furnish about the same percentage of permanent cures as surgical treatment in the best hands. The advantages of X rays were: (1) there was no mortality resulting from the treatment; (2) patients would submit to it more readily than to operation; (3) it was applicable to inoperable and post-operative cases. It had the disadvantage, on the other hand, that the treatment was prolonged and that there was a risk of atrophic changes and telangiectases in the irradiated skin. There was ample clinical evidence from the amelioration which followed radiotherapy to justify its employment on rational grounds as a most useful adjunct in the treatment of Graves's disease.

Dr. T. G. Hardman said that he was an enthusiastic advocate of X ray treatment in exophthalmic goitre. In June, 1925, he had been able to collect about 60 cases, and follow their course for several years back. On the whole, he thought, the results were very satisfactory. Over 75 per cent. of the patients were cured of their symptoms, 22 per cent. were greatly improved, and the rest were slightly improved. There had been no deaths. Some of his cases he had been unable to trace, but he had since learned that two of them had been successfully treated by operation. He thought that too much emphasis could not be laid on the fact that radiologists only advocated the use of X rays as part of medical treatment. The success of radiotherapy depended very largely on the strictness of the medical régime. The cases which did best were those which were treated in private, where they could have the absolute rest and regulated life which were so essential. Greer, of America, divided hyperthyroid cases into four groups: (1) those with simple hyperthyroidism, in which he claimed to get 100 per cent. cures; (2) those with acute exophthalmic goitre, in which he claimed to get almost miraculous results; (3) those with chronic exophthalmic goitre, in which treatment was much more difficult (cases which came for treatment within 6 or 12 months of the development of symptoms did well, but if they came later they were much more difficult to treat and more likely to relapse); (4) cases of ordinary goitre, in which he advocated surgical treatment altogether. In X ray treatment there was no immediate mortality; the treatment was easy to carry out, and there was no scarring such as was found after operation. If it was unsuccessful, it did not prevent patients from being operated on afterwards, although some surgeons said that operation was made more difficult by the formation of fibrous tissue as a result of radiotherapy. He personally thought that every patient should be given a chance of X ray treatment before being submitted to the risk of operation—however small this might be.

Prof. J. M. O'Connor said that undoubtedly the thyroid gland had its use and significance in the body, but it was very hard to say what its use was. It had been thought at one time that exophthalmic goitre was due to an excess of adrenalin in the blood, but this idea had been proved wrong. The estimation of basal metabolism seemed to him a very heavy weapon to use for examination of a disease which could be examined by much more simple methods.

Mr. H. Stokes said that he did not think statistics of much value in discussing the treatment of exophthalmic goitre, because it had only recently been recognised that there were two varieties of the disease—toxic adenoma and Graves's disease. The mortality in toxic adenoma was just as high as ever, but with the use of iodine in Graves's disease the mortality had come down to 2 per cent. The accounts of treatment at the American clinics gave the impression that patients were admitted in a very grave condition, were given iodine for three or four days, were then operated on, got up within a week, and within a fortnight were able to leave the clinics and go back to work and lead a normal life. He had operated on three cases of Graves's disease recently, and in one case, after three months, the patient had been able to return to work and was now perfectly well. There were undoubtedly cases of well-marked exophthalmic goitre which got well in a remarkably short time, but they were apparently a mixture of toxic adenoma and Graves's disease.

Prof. T. G. Moorhead said that before it was possible to estimate the value of any treatment in any disease, it was necessary to know what was the natural course of that disease without treatment, or (in the present case at any rate) when treated only by the simplest medical methods such as rest and sedatives. Information on this point was very scanty. No reliable figures existed showing the actual mortality incidence. Campbell, in a paper communicated to the Association of Physicians a couple of years ago, had determined the death-rate throughout Great Britain and Ireland, and estimated that roughly ten persons per million living died of exophthalmic goitre annually, though there was considerable variation in different districts. In 1922, 22 deaths had been recorded in the Free State; in 1923 there were 18 deaths. It was worth noting that 24 of these 40 deaths occurred in people over 40 years of age, from which it might perhaps be deduced that death usually followed many years of illness, since most cases of Graves's disease were encountered in the earlier years of life. The Free State figures worked out at roughly seven deaths per million living. Quite plainly, however, none of these figures gave any information about the number of deaths in proportion to the number of people who suffered from the disease. Marion Read, who observed 100 cases over a period of about six years, reported altogether six deaths, and four of these immediately followed surgical treatment. From these scanty figures it appeared that the medical death-rate was, at any rate, not high. It was equally difficult to get reliable figures about recovery from the disease. It was common knowledge that many cases recovered completely without any treatment, and that, on the other hand, many drifted on as chronic invalids. The general opinion was that about 50 per cent. of recoveries might be expected, and any treatment that did not improve on that figure might be regarded as of no value. Kessell, of New York, indeed, stated that in 82 per cent. of cases observed by him, economic recovery occurred in from four to six months, without any special treatment; but he admitted that many of his recovered patients still suffered from considerable disability, and few would agree with his statement that practically all cases tend to recover if left alone.

In considering surgical treatment, said Prof. Moorhead, it was necessary to distinguish between immediate and remote results. The immediate mortality in some clinics was very low; in the Mayo Clinic and in Cleveland the mortality was only about 1 per cent. On the other hand, Kessell and Hyman reported an operative mortality of 9·3 per cent. in a group of cases collected from various clinics, and Marion Read, in a small number of cases, found a mortality as high as 31 per cent. From this it was clear that, although surgery under special conditions was comparatively safe, it was by no means a treatment to be universally adopted. The ultimate results following operation were very difficult to arrive at. Some surgeons led people to believe that their cases were completely cured in a month or so after operation; but Marion Read, reporting on 25 cases followed for from three to five years after operation, described only two as cured and nine as improved. Twenty-five cases was a very small number on which to base any statements, but the conclusions derived some importance from the fact that the cases were definitely followed up and a description was given of their condition some years after operation.

Speaking of X ray treatment, Prof. Moorhead said that he felt very enthusiastic. In a series of 51 private cases which he had reported in June, 1925, he had been able to follow up 44. Of these, two definitely did badly, showing no response to treatment, and one died of influenzal pneumonia; but there were 34 complete cures, and seven other patients were very much improved. That is to say, there were 77 per cent. of cures and 15 per cent. were improved—a total of 92 per cent. good results. These figures supported those given by Dr. Hayes, and pointed strongly to a combination of medical and X ray treatment as giving the best possible results—results, moreover, unattended by any danger. In treating cases in this way he had found that acute cases did much better than milder and more chronic cases, and that private patients, on the whole, did better than those in hospital. Details of treatment were extremely important. The patient should remain in bed, on a restricted protein diet for the first month, and sedatives should be given as required, quinine bromide being particularly useful. As regards the application of X rays a double course was all important, and he advised two periods of treatment, each of about three weeks duration, with an interval of a month between the two; the thymic region should be irradiated as well as the thyroid. Of late he had been using lugol solution as an addendum to his treatment. It was customary to say that iodine was of particular value in preparing patients for operation. That was doubtless true, but it was also of value, he thought, in hastening recovery by means of X rays. When iodine was used the pulse-rate came down more rapidly than otherwise, and the thyroid gland soon became harder. In most cases the patients were practically well within six months of the beginning of treatment; and by well he meant completely well—that is, they had gained weight, had a normal pulse-rate, no tremor, no sweating, and were free from nervousness. Traces of goitre often persisted, and often some exophthalmos; but these were unimportant when other symptoms were absent. All his cases claimed as cures were able to lead normal lives and were without disability.

Dr. H. F. **Moore** commented on how little was known of the actual physiology of the thyroid gland, and hoped that the discovery of thyroxin would prove a stimulus to renewed physiological research. The pathology of the gland was in an even worse state of confusion; as a classification of types of enlargement, he thought Aschoff's the most suitable. He summarised recent advances in knowledge of thyroid function, speaking particularly of Kendall's work on the thyroxin molecule and its physiological properties. The effect of iodine in hyperthyroidism was of great interest, and any evaluation of treatment should be controlled by clinical observation and estimation of the basal metabolic rate. His cases were all treated under such control by general treatment, iodine, and X rays, but he did not hesitate to have recourse to surgical treatment where he thought it necessary.

Sir **William de C. Wheeler** said that the literature of exophthalmic goitre had become quite unwieldy. In the surgery of the disease Albert Kocher had been the great pioneer. Of the cases treated between the years 1883 and 1889 Kocher stated that 76 per cent. were cured, and that the mortality was 6·7 per cent. In 1910 the mortality in Kocher's clinic had been reduced to 4·5 per cent. During the last 15 years immense strides had been made in surgical treatment, which had brought the mortality in the clinics of Mayo and Crile down to about 1 per cent. The mortality following operation for toxic adenoma was much higher—about 3·5 per cent. The results of surgical operation could be accurately estimated, but the ultimate mortality from failure of medical treatment was difficult to ascertain. Sir William Wheeler said that he had referred to the records of 76 thyroid cases operated upon since 1910, but did not consider his statistics accurate because there was confusion between some of the cases of toxic and non-toxic goitre in the hospital records. He had had two deaths from true Graves's disease during this period. One of them was from acute hyperthyroidism in the days before iodine was administered as part of the pre-operative preparation, and the other was due to mechanical difficulties in breathing following an extensive operation. Recent technique had eliminated this danger. In nearly all of the cases operated on by him medical treatment and radiotherapy had been tried first; but it was quite possible that a number of them had not submitted faithfully to the directions of the physicians. Operations were not shirked in any instance because the disease was advanced and the patients were grave surgical risks, but in such cases the operative procedures were very carefully graded. He emphasised the fact that Graves's disease was a disease of cycles; that the stage of development was followed by one of maximum intensity, and that then there was retrogression and remission. In the quiescent period operation was comparatively safe, but during a crisis operation should never be done. He was struck by the dramatic improvement which sometimes followed a few days after operation. The statistics given in the literature were often faulty owing to the comparison between inefficient surgery and efficient medicine, or efficient surgery and inefficient medicine. To obtain anything like accurate information, the statistics of the best authorities, surgical, medical, and radiological, should be balanced. If this were done it would be found that the honours were easy. In most cases a combination of methods was desirable. Lugol solution was an immense help in preparing patients for operation and it would control post-operative remissions. About 5 per cent. of patients did not react to the administration of iodine.

Dr. R. **Stumpf** said that it was found that if cases considered most favourable for operation received a preliminary X ray treatment about a fortnight beforehand, the operative risk was lessened. He reviewed a series of cases of which the majority were treated by X rays alone, in 90 per cent. of which there was either cure or great improvement; if there was no improvement after several irradiations, then operation was done. He had found that ill-effects were more likely to occur after the use of superficial rays than with deep rays. Cases had been known in which adhesions were found at operation although the patients had never been X rayed, and he felt that their presence should not be considered an insurmountable barrier to operation. He always irradiated the thymic region, even when no gland was present, and in cases of simple goitre he always preferred X ray treatment to operation, even in juvenile cases. He had seen several cases of simple goitre in which the tumour had entirely disappeared.

Mr. A. CHANCE referred to the special circumstances of patients of the hospital class, which often prevented adequate medical or X ray treatment. It was in these cases, he felt, that operative treatment showed to advantage. The object of X ray or surgical treatment was to destroy a certain portion of the thyroid gland, and, if this could be done safely, it was desirable, because it could certainly be done more speedily by surgical means than by any other. It was unquestionable that in certain clinics where these cases were handled by one team, as in the Mayo and Crile clinics, the mortality was in the region of 1 per cent.

Dr. M. F. O'HEA had treated a large number of cases of exophthalmic goitre by X rays and thought that his results were roughly about 75 per cent. of cures. Referring to the condition of patients after treatment, he said that after the first treatment there seemed to be an exacerbation of symptoms; but this, he thought, was the result of fright rather than of the treatment itself.

Dr. W. C. STEVENSON said that for a long time now he had not used superficial rays in cases of exophthalmic goitre, because these rays did not affect the pathological cells which were found in exophthalmic goitre. If deep X rays were given it was impossible for the cells to escape some effect; these rays tended either to destroy the cells altogether or to stimulate them to return to a more normal condition. The fibrous tissue which was produced by X rays was not the cause of the cure but the result of it. Deep X rays were also more efficient because they penetrated deeper. In some cases radium had an advantage over X rays, for in cases where very slight but very continuous stimulation was required this could be given better by radium than by X rays.

Mr. W. PEARSON said that he had not found that X ray treatment made operation any more difficult. Fibrosis was produced, but it was in the stroma of the gland itself, and made no difference as far as operation was concerned. He, personally, had never had any difficulty in getting the thyroid gland out cleanly and bloodlessly in cases in which there had been fairly extensive X ray treatment.

Dr. HAYES, replying, referred to the possible rôle which thyroxin played in exophthalmic goitre. If antecedent X ray treatment really caused adhesions and rendered operation more difficult, this was a thing which radiologists should definitely try to improve. He did not think that X ray treatment alone would cure exophthalmic goitre, and the more he saw of the condition, the more convinced he was that a radiologist would not cure a case unless he was also a physician, and a good physician. The most essential part of the treatment was the medical régime.

## EDINBURGH OBSTETRICAL SOCIETY.

AT a meeting of this Society held on March 10th, Dr. R. W. JOHNSTONE, the President, in the chair, Dr. WILLIAM FORDYCE gave a short note on a case of

### *Ectopic Gestation with Unusual Clinical Features.*

The patient, a multipara of 36 years, was admitted into his ward with a history of severe vaginal hæmorrhage following what was supposed to have been an incomplete abortion, as she had three weeks previously passed a lump per vaginum as big as her closed fist. This was corroborated by her medical attendant. After her admission she was examined under chloroform and the os was found to be patulous, but nothing was found inside the uterus, although there was a somewhat foul-smelling discharge. The patient progressed satisfactorily for a week; there was no further discharge and the temperature remained normal. She then began to complain of colicky pain in the right hypochondrium and became slightly jaundiced. Cholecystitis was diagnosed and a laparotomy was performed two weeks after her admission to hospital. The abdomen was found to be full of bright red blood and a fœtus was found later amongst the clots. In all probability the sac had been ruptured by bimanual palpation immediately before operation.

In reviewing the case Dr. Fordyce said that he thought it must be classed as a "combined" gestation (both intra- and extra-uterine), for on examination on admission, though she was very stout, there was nothing like an ectopic gestation to be palpated, and yet before her operation a swelling could be felt distinctly. The pain and tenderness in the right hypochondrium was very difficult to explain.

Prof. CARLTON OLDFIELD (Leeds) read a communication on

### *Symptoms without Signs.*

This title, he said, was chosen because there was no more common case than the patient who complained of symptoms, but in whom no physical signs could be detected. Out of 1200 patients examined by Prof. Oldfield only 434 (36 per cent.) showed any gross disease, and this he deemed to be due to the majority of cases being functional. The usual symptoms in such functional cases were headache, backache, weariness, sleeplessness, and frequency, precipitancy or incontinence of urine. For such conditions curettage was unnecessary and harmful, as also were operations such as ventrosuspension, cervical repair, and appendicectomy. Backache was found in 67 per cent. of all Prof. Oldfield's cases, but in only 34 per cent. of these was any organic disease present. Retroflexion was present in only a few more cases than anteflexion, which confirmed the opinion that retroflexion, though often accompanying backache, was not the cause of it. Cervicitis (with or without laceration) and endometritis were not noted as being in any way definitely associated with backache; though, as all these complaints were common, they were bound to occur together in many cases. Backache, therefore, was usually a functional complaint. Incontinence of urine was then discussed, the incontinence being of the active kind and not passive as in a vesico-vaginal fistula. In 12·8 per cent. of Prof. Oldfield's cases there was incontinence, and yet 29 per cent. had urethrocele; among the cases of incontinence 28 per cent. had urethrocele and 28 per cent. prolapse. Prolapse was present in more cases with incontinence of urine than without, and therefore was probably a causal factor, though only 7 per cent. had cystocele; but urethrocele, on the other hand, occurred more frequently in cases without incontinence. Incontinence was, he considered, purely functional, which was proved to his satisfaction by the fact that application under anæsthesia of the electrocautery cured nearly every case. This would have been impossible if it were due to pathological or anatomical reasons, as was generally supposed. Speaking of retroversion of the uterus, Prof. Oldfield quoted the statistics of Dr. MacGregor Young. 1000 puerperal uteri were examined on the twelfth day after labour and retroversion was found in 50 cases, but six months later only two were found to be still retroverted. Pessaries might relieve symptoms sometimes, but it was probable that prolapse was present in such cases. He advised that the words retroflexion and retroversion should be discarded; pessaries would then cease to be used or operations to be done in such cases. Many women were made unhappy by being told that their womb was twisted. In conclusion he touched on the pernicious vomiting of pregnancy, which he considered always to be functional; he advised treatment by suggestion and feeding, which in his experience had always been successful.

Dr. F. J. BROWNE read a paper on an experimental investigation into

### *The Ætiology of Accidental Hæmorrhage and Placental Infarction.*

After briefly discussing the various views held on the cause of accidental hæmorrhage and the relationship between it and toxæmia, nephritis, and liver changes, he described the origin of the present research. In

1923, during an experimental investigation into the paths of intranatal infection in the newly born infant, a rabbit (20 days pregnant) was injected with an emulsion of *B. pyocyaneus* in saline. It was found six hours later to be bleeding profusely from the vagina. Under ether anæsthesia the abdomen was opened and a large retroplacental hæmatoma was discovered, entirely, or almost entirely, separating the placenta from its attachment. On microscopic examination an acute nephritis was found affecting the glomeruli and convoluted tubules. Attempts were made to reproduce this result on 34 subsequent occasions, but without definite result. Some factor essential for success was evidently missing. From clinical observation of patients Dr. Browne was impressed by the frequency with which in cases of accidental hæmorrhage he could obtain a history pointing to chronic nephritis. In one case of concealed hæmorrhage there was no doubt about the presence of chronic nephritis, as albuminuria had been present with accidental hæmorrhage in the previous pregnancy. The patient had been followed up in the interval between that and her next pregnancy and it was found that the albuminuria had persisted. In this pregnancy albuminuria was present from the start and at the seventh month she was admitted to hospital with a concealed hæmorrhage. Dr. Browne therefore believed that if he could set up a chronic nephritis and introduce *B. pyocyaneus* in the pregnant rabbit so suffering he should be able to produce accidental hæmorrhage. In order to cause chronic nephritis sodium oxalate was used in 1 per cent. solution according to the method described in 1924 by Shaw Dunn, Haworth, and Jones.

Thirty-five rabbits were treated during three months by injecting them intravenously with the oxalate at frequent but varying intervals. The blood-urea was regularly examined and the rise of blood-urea was taken as the clinical index of the onset and duration of nephritis. Eight rabbits died during the experiment, and histological examination of the kidneys revealed an acute nephritis chiefly affecting the convoluted tubules. In animals that had been under treatment for eight weeks or more a very well marked interstitial nephritis was found as well. After three months' oxalate treatment the remaining rabbits were mated, and at the twentieth day of pregnancy a small dose of sodium-oxalate was again given. Next day the blood-urea was examined and a small dose of emulsion of *B. pyocyaneus* in saline was given intravenously. This experiment was tried in six cases in succession and in all of them it was successful; more or less profuse hæmorrhage started within a few hours of the injection. After bleeding had continued for some time the rabbit was killed by chloroform and the condition of the uterus and placenta examined. All the placentas (seven in number) showed typical red infarcts exactly resembling those found in the human subject in cases of albuminuria. In one of the placentas there was a large clot between the membranes and the cornual wall, while there had been several profuse external hæmorrhages. There had therefore been produced accidental hæmorrhage, external and concealed, with hæmorrhage in the uterine muscle and infarction. These conditions, singly or in combination, could be produced at will and this particular experiment was therefore discontinued.

Dr. Browne also described other experiments that had been carried out since. These had shown: (1) That the dose of oxalate at the twentieth day of pregnancy was unnecessary, for bleeding could be produced by injecting *B. pyocyaneus* alone, provided the kidney had been previously damaged by injecting oxalate over a prolonged period causing a chronic nephritis. The mere injection of *B. pyocyaneus* was now sufficient to bring about an acute exacerbation of the nephritis, as shown by rise in blood-urea, and lead to hæmorrhage. (2) A previously existing chronic nephritis was unnecessary, for if an acute oxalate nephritis were produced and organisms then introduced bleeding occurred. These two alternative methods seemed, however, to be somewhat less certain than the method first adopted. (3) The coliform group of organisms seemed to be the most potent in causing a positive result. (4) In every case in which hæmorrhage had so far occurred, if a chronic nephritis were previously existing, an acute or subacute exacerbation of the nephritis preceded the bleeding.

## BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held on April 1st, Mr. H. J. WALKER, the President, in the chair, Dr. JAMES MENNELL read a paper on

### *The Principles and Practice of Manipulative Surgery.*

He drew attention to the dictum quoted by Wharton Hood as being always in the mouth of Hutton, that "the twist is the thing." In all joints, he said, with the exception of the hip-joint, it was possible to perform some movement not under the voluntary control of the patient. The most conspicuous movement of this type was that which resulted on the application of tension; and it was often useful to perform those movements as a preliminary to carrying out the normal movements of the joint. Manipulative treatment had suffered a set-back owing to the too rigid adherence to Hilton's teaching of rest and pain. The mistake had been made in the past of failing to realise the essential difference between movement and function, a distinction so ably drawn in the work of Lucas-Championnière. Dr. Mennell put in a claim for the more general recognition of the osteopathic definition of a lesion, which he quoted as being "the immobilisation of a joint in a position of normal movement," the immobilisation being due to: (1) locking within a joint, without actual displacement, or the formation of adhesions; (2) definite adhesions within the joint; (3) adhesions in the soft tissues around the joint; (4) adhesions in the extra-articular structures; (5) adaptive shortening in the elastic tissue of the muscles which control the movements of the joints; or (6) hysteria. He drew particular attention to the danger of putting a joint through its full range of anatomical movement when limitation of movement was marked and of long standing. In these cases it was merely desirable to pass the first dead point, and then to allow the patient to regain the increased freedom of movement before an attempt was made to gain a yet wider range as the result of subsequent manipulation. After-treatment was also essential. Dr. Mennell ended his paper with a plea for more scientific consideration of lesions of joints of the back, condemning the practice of readily dubbing every aching back as neurasthenic instead of trying to form an accurate diagnosis of the physical lesions present, and giving them appropriate treatment. He then gave a demonstration of the manipulation applicable to various joints.

Dr. H. M. GALT showed microscopical slides.

---

ROYAL INSTITUTION.—On Tuesday, April 20th, at 5 15 P.M., Prof. J. Barcroft will lecture on the Spleen.

BOSTON CITY HOSPITAL.—The report of this great American hospital for the year ending Jan. 31st, 1925, which has just been issued, shows that the total expenditure exceeded £337,000, and that the daily cost of in patients was 15s. per head. The very large new out-patients' department contains a great number of small examining rooms, "self-respecting citizens who are compelled to resort to a hospital clinic being entitled to the same privacy that they would have if treated in a physician's office" Each of these rooms contains a lavatory basin, and, it is added, "the physician is expected to wash his hands after the examination of each patient"

PAPWORTH TUBERCULOSIS COLONY.—This valuable and successful colony has just celebrated its tenth anniversary. A beginning was made at Bourn, in Cambridgeshire, with 12 patients; there are now more than 200, and in the village settlement connected with Papworth Hall 70 or more settlers and their families occupy separate houses. The village is recruited from patients who have been in residence for six months, and it now has over 500 inhabitants, of whom 85 are children. These settlers are busily occupied in carpentering, poultry-farming, printing, cabinet-making, upholstery, shoemaking, tailoring, or sign-writing, and there is now a village store which employs some of the women patients.

# Reviews and Notices of Books.

## NEURITIS AND NEURALGIA.

By WILFRED HARRIS, M.D. Cantab., F.R.C.P. Lond., Senior Physician to St. Mary's Hospital and to the Hospital for Epilepsy and Paralysis, Maida Vale. London: Humphrey Milford, Oxford University Press. 1926. Pp. 418. 12*s.* 6*d.*

Dr. Wilfred Harris has compiled a useful and practical volume of which the contents have an even wider range than is indicated in the title. Pain, of course, is always nerve pain, and there are very many nerves in the body—cranial, peripheral, visceral; hence in dealing with neuralgia and neuritis the author of necessity covers much clinical ground. Further, many paralyses are the result of nerve involvement. The reader need not, therefore, be surprised to find that such diverse conditions as dislocation of the shoulder, adhesions in joints, hiccough, myoma cutis, convulsive tic, and spondylitis are assigned a place in this compendium of neuritis.

The author indicates at the outset the loose way in which the terms are commonly employed; they are in many instances a complete misnomer. Nor is the distinction between neuritis and neuralgia always clear. Dr. Harris seeks to define neuralgia as a pain radiating beyond the limits of a local (filament or fibre) neuritis, this latter focus being in his view a constant finding. Objective proof of the reality of this terminological explanation would, we imagine, be difficult; conversely to his contention that neuritis precedes neuralgia (the latter he would like to think is always reflex), it might be held with justification that neuralgia precedes neuritis. However this may be, discrimination is less important than might appear; there are clinical methods of differentiation, but sensory neuritis is painful just as is neuralgia. All the common and many rare varieties—for example, meralgia paræsthetica or Bernhardt's syndrome—are described in succinct yet satisfying fashion; it is pleasing to find valuable information, with bibliographical references, in regard to out-of-the-way conditions such as hæmatoporphyrinuric polyneuritis, uveoparotitic paralysis, and so forth. Indeed, expecting so much from the excellence of the volume, we are the more surprised to find no apparent description of, or reference to, metatarsalgia or Morton's syndrome. This clinical condition alone, we think, has slipped through the meshes of Dr. Harris's all-embracing neuralgia net.

As for the topics that the author has made his own —viz., the treatment of cutaneous and deep neuralgias by alcoholic injection methods—they are handled in a masterly and authoritative manner. He may well be congratulated on his experience and on his success. Both practitioner and specialist should add this vade mecum to their libraries; it is full of valuable clinical and therapeutic data, and is well illustrated.

## THE SURGERY OF CHILDHOOD.

By JOHN FRASER, *M.C.*, M.D., Ch.M., F.R.C.S.E., Regius Professor of Clinical Surgery, University of Edinburgh; Consulting Surgeon to the Royal Hospital for Sick Children, Edinburgh. London: Edward Arnold and Co. 1926. In two volumes. Pp. 1152. 42*s.*

OF late years no text-book of the surgery of children has appeared in this country, and this work will, therefore, be examined with keen interest. It may be said at once that Prof. Fraser has been completely successful in presenting a readable and well-balanced account of the subject. There is abundant evidence that the book is not, like so many text-books, merely a compilation. The personal touch appears often in its pages, revealing the wide experience of the author and enhancing the value of his conclusions. There is, indeed, little which calls for criticism; here and there we notice an omission for which the author may have a good excuse. For instance, decortication for old resistant empyema is not described, nor is litholapaxy given as an alternative method to suprapubic cystotomy for stone in the bladder. Sometimes new methods are described which should only be mentioned for condemnation, such as the "closed method" of treating acute appendicitis in children. The only operation for ectopia vesicæ given is the intraperitoneal one of successive transplantation of the ureters, and we are not told what to do with the exposed vesical mucosa remaining behind. We are glad to see diaphysectomy for acute osteomyelitis condemned, and also, in nearly all cases, bone-grafting for Pott's disease of the spine. There are a few misprints—for example, on line 10, p. 700, "cord" appears for "canal"; on p. 638, line 27, "caries" for "carious"; and on p. 582, line 19, "fustula" for "fistula."

The book will certainly meet with a good reception from all interested in children's surgery.

## THE HISTORY OF PROTOZOOLOGY.

By F. J. COLE, D.Sc., Professor of Zoology, University College, Reading. London: University of London Press. 1926. With 1 plate. Pp. 64. 3*s.*

THE history of the progress of natural knowledge teaches us two lessons—that discovery is a process and not an event and that anyone may come across something fresh at any time. Prof. Cole's interesting lectures illustrate these points with material which is more or less familiar both to medical zoologists and to microscopists. One wonders whether Dallinger and Drysdale's description of the production of almost invisible heat-resistant "spores" by a flagellate may not possibly be more correct than recent criticism has been willing to allow; something of a similar sort has been found for some of the ultramicroscopic viruses.

A subsidy from the Publication Fund of the University has made the book very cheap, and it should be read widely.

## THE CHEMISTRY OF DRUGS.

By NORMAN EVERS, B.Sc., F.I.C., Chief Chemist to Messrs. Allen and Hanburys, Ltd. London: Ernest Benn, Ltd. 1926. Pp. 247. 32*s.* 6*d.*

THE paper cover of this imposing and attractive-looking volume displays the statement that the chemical aspect of drugs has never before been dealt with in one volume, whilst the preface states that the author has endeavoured to give a description of substances used in medicine from the standpoint of pure chemistry. The reader is therefore justified in hoping for a work comparable, say, to Die Arzneimittel-synthese and may be disappointed.

The volume is divided in a logical way into two parts, the first dealing with synthetic drugs and the second with drugs of natural origin. In the first section hypnotics, antipyretics, local anæsthetics, and so forth are described. The author states in his introduction that the drugs dealt with have been chosen "either as being of established reputation, or as being of special interest to the chemist." The selection appears, however, to have been rather limited, and confined mainly to drugs well established by English firms. In the scanty space—only three and a half pages—devoted to organic compounds of arsenic, the references to the literature are inadequate, and stovarsol is not even mentioned. Antimony compounds receive one paragraph, whilst mercurial drugs are despatched in two pages. The second part of the book is devoted to drugs of natural origin. The alkaloids are treated in a slightly more respectful manner, but the account cannot be regarded as in any way complete. Drugs of animal origin also receive inadequate notice, and the section on insulin is poor. Methods are referred to so briefly that frequently their underlying principle is not made plain. The author shows undue credulity in the section on thyroid preparations; for instance, the acetonitril test is referred to as being the last court of appeal as a test for potency.

Regarded as an expanded chemical drug catalogue, with graphic formulæ and a few details about them, this book will cause no disappointment and may, indeed, be useful. For example, the section on hypnotics will be found of value by the practitioner, and Appendix II. is really informative. It consists of a table showing the official trade names of drugs, their chemical constitution, and their main physiological action. For the production of the volume we have nothing but praise.

### PRACTICAL PHOTO-MICROGRAPHY.

Second edition. By J. E. BARNARD, F.R.S., F.Inst.P., F.R.M.S., Lecturer in Microscopy, King's College, London; Director of the Department of Applied Optics, National Institute for Medical Research; and FRANK V. WELCH, F.R.M.S. London: Edward Arnold and Co. 1925. Pp. 316. 18s.

THE first edition of this work was published in 1911, yet, as the authors say, photo-micrography has not advanced so much since then as to necessitate the complete rewriting of the book. It is true that the general level of microscopes and photographic apparatus may be higher now than 15 years ago, but individual microscopes and lenses are no better to-day than they were then. The authors have, therefore, devoted themselves to the consideration of method rather than apparatus, and have produced a volume which cannot fail to be of the greatest value to those interested in this technique. Every aspect of the subject is fully dealt with, but by the exercise of a commendable sense of proportion the manual remains of reasonable size. We have looked in vain for serious omissions; possibly a comparative scale of the speed values of the commoner plates in use would be appreciated. The book is essentially practical and is written simply and clearly, so that no one should have any difficulty in following the authors' instructions. Finally, the illustrations are excellent, and the beautiful examples of what can be done with photo-micrography are stimulating.

### CLOUDS AND WEATHER PHENOMENA.

By C. J. P. CAVE, M.A. Cambridge: At the University Press. 1926. With 47 figures. Pp. 32. 5s.

WEATHER phenomena are being more closely observed to-day, and there are many books on meteorological subjects which contain full information on the appropriate instruments and their use and on the principles of forecasting from weather maps. But the phraseology in which to describe the changing pageant of the sky is not known to many who try to communicate observations upon what they see, and this small volume, with its accompanying illustrations, will be found useful in this direction. Another class of reader to whom a more direct appeal is being made is formed by artists of all sorts, for the small photographs illustrate a very large variety of skies, the clouds of the various sorts and shapes indicated by their names massing themselves together, falling apart or fading in very typical manner. Skies that we have all had opportunities of seeing are reproduced, but as the photographs of clouds have been taken with the intent to get as much detail as possible of the cloud structure, the illustrations are dramatic. It is cloud structure which many painters fail to render correctly, or make little attempt to render; the changes in a sky at all cloud laden and at all influenced by wind are so rapid that what may be termed the architectural make-up of the vapours must often fail to obtain recognition on canvas or paper. The photographs, as the author states, were not taken with the intent to make artistic pictures, and as far as their utility to artists is concerned they should be of great use to students of landscape in providing many significant conditions of sky under which cloud phenomena, with their endless and rapid modifications, will be found to range themselves.

### CARE OF THE FEEBLE-MINDED.

*The American Association for the Study of the Feeble-Minded.* Proceedings and Addresses of the Forty-ninth Annual Session held at Raleigh, N.C., May, 1925. Comprising the *Journal of Psycho-Asthenics* xxx. Published by the Association. 1925. Pp. 360.

THE care of the feeble-minded has of recent years become a specialty and, like all new specialties, it has developed a literature of its own. The more the problem is investigated the more it becomes apparent that the workers are but at the beginning of their labours. At the American Conference held last summer the mental defective was discussed from all angles by workers of all kinds, and Dr. G. B. Smith's presidential address aptly urged the importance of amalgamating the modern trends in medicine, politics, economy, sociology, and law. The more strictly medical contributions include a review by Dr. H. W. Potter of the literature on the morbid anatomy of the mentally deficient brain, and a paper on the Understanding of the Feeble-Minded, by Dr. T. Haines. Dr. C. B. Davenport and Miss G. Allen conclude that the production of a Mongoloid dwarf requires the combination of three or more of a large number of favouring hereditary and environmental elements, and Dr. R. B. Bean compares the anatomy of the Mongol with that of the hypomorph white type. Dr. L. H. Bartemeier discusses psychoses in the feeble-minded, and Dr. Bramham psychiatric problems in the care of mentally defective children. In other sections Mr. B. W. Spilman reviews the difficult problem of religious training for these children, while Dr. Murdoch, in a paper on the Relation of Mental Deficiency to Morals, Religion, and Ethics, points out that virtue and vice do not depend on intelligence, and much can be done for the easily-moulded moron by religious and social institutions. Miss L. G. Galbraith and Miss M. S. Walker describe methods of organising work in classes for the mentally defective, and Dr. Gladys Ide discusses motivation in school work.

In his paper on Institutional Training of the Defective Delinquent, Dr. W. N. Thayer describes the procedure at the Napanoch State Institution, of which he is superintendent. During a fortnight's quarantine the delinquent is subjected to every possible examination and is usually found to have fallen far short of his possibilities. Any physical defect is corrected as far as possible, and an educational campaign instituted wherein manual and trade instruction is carried to the highest point possible but academic education through lower grades only. For the formation of social habits an even discipline is enforced, drilling-in the idea of obedience and the realisation of the benefits it confers. Supervision is relaxed gradually, and the delinquent is finally placed on parole in a colony and then in a suitable environment outside. The criticisms of present-day parole systems offered by Dr. Thayer are that it is preceded by inadequate preparation for freedom within the institution and is frequently tried under unsatisfactory employers, under too difficult conditions, or under inadequate supervision. Dr. H. M. Adler and Miss M. R. Worthington discuss the delinquents of Illinois and conclude that there is no correlation between crime and intelligence, and Dr. H. A. Cotton discusses the Relation of Focal Infections to Crime and Delinquency, basing his observations on the experience of the Psychiatric Clinic for Correctional Institutions in New Jersey, where the problem has been studied for seven years. He emphasises the danger of passing a child's mouth as "fit" from an inspection of the teeth; impacted third molars, even in childhood, are almost invariably infected, and are a frequent cause of backwardness or vague ill-health. X rays should also be applied to the gastro-intestinal tract, and colon stasis is treated at this clinic by surgical methods. About 80 per cent. of their female cases suffer from menstrual disorders, mainly due to infection of the cervix. Similarly, colon bacilli and cocci are frequently found in the seminal vesicles of the male, quite apart from any venereal infection. Removal of septic foci produces a remarkable improvement in the emotionally unstable as well as in the definitely defective. Mr. G. M. Wilson discusses the part of Psychological Tests in the Diagnosis and Analysis of Mental Deficiency, reviewing critically the many different test schemes that have been devised in recent years. In discussing the Functions of a Clinical Psychologist in an Institution, Mr. Ll. N. Yepson deplores the tendency of these officials to occupy themselves entirely with academic research; they should identify themselves with the every-day life of the institution and determine for each inmate just what type of training and environment will bring the utmost possible out of him. Dr. Mary M. Wolfe discusses the Relation of Feeblemindedness to Education, Citizenship, and Culture, and stresses the results of training the feeble-minded in public schools, particularly the inferiority complex, which is bound to develop and probably plays a significant part in defective delinquency. Dr. T. H. Haines inquires carefully into the relation between mental defect and poverty with the aid of statistics compiled by the National Committee for Mental Hygiene, and finds six times as many defectives among the poor as among school-children generally.

In all some 30 papers, mainly non-technical, are printed in this volume, and anybody who is interested in recent work among defective children will welcome their appearance in one cover.

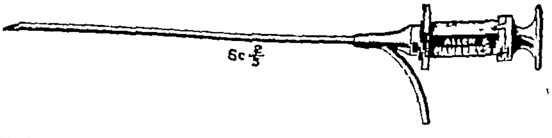
## JOURNALS.

BRITISH JOURNAL OF CHILDREN'S DISEASES. Vol. XXIII. January–April.—Mr. Macleod Yearsley contributes a paper on the Development of Speech in the Normal Child based on almost daily observations of his own child for a period of over three years. He maintains that the first year is spent in methods of communication which are partly animal and partly primitive human, while the second year is devoted to the completion of a vocabulary and experiments therewith, the third year being occupied in perfecting and correcting.—In a paper on Chronic Abdominal Pain in Childhood Dr. K. U. Toverud shows that chronic constipation in some children gives rise to a picture suggesting a severe disease, recurrent abdominal pain and general malaise being the predominant symptoms. The principal cause of the condition is concentrated food which consists of readily digestible material, so that its utilisation is complete in the intestinal tract and very little or no residue is left to stimulate the intestine to peristalsis. Another cause is to be found in the bad habits of the child who is too busy playing to take time to empty his bowels. The symptoms readily disappear as soon as the child is given a diet consisting of whole wheat bread, lactic acid milk, much raw fruit, large quantities of vegetables, besides some fish and meat. —In a paper on Observations on Goitre in Childhood Dr. H. Leslie Cronk comes to the conclusion that the causes of goitre in children may be: (1) a hereditary or early acquired diminution in secretory activity of the thyroid; (2) the relative increase of weight of the body causing increased need of thyroxin for metabolism; (3) some factor which affects the tonsils in such a manner that the rise in prevalence of enlarged tonsils coincides with a diminution of goitre prevalence, and exerts such an effect on the latter that the enlarged tonsil-rate at times over-rides the effect of increased metabolism required for increased body-weight.—In a paper on Pneumothorax in Young Children, with an account of a case, Dr. Alan Moncrieff reviews the literature and points out that though many of the recently recorded cases seem to have been tuberculous in origin, tuberculosis, especially in young children, is not a common cause of pneumothorax. In his own case, which occurred in a male infant of 1 year 10 months, the favourable issue and negative Pirquet test suggested that the case was not tuberculous and that the condition was probably caused by the rupture of a subpleural emphysematous vesicle in the course of a bronchopneumonic process in the right lung. The absence of any pus in the pleural cavity was against rupture of a subpleural abscess which is the commonly accepted cause in post-pneumonic cases.—In a paper on Palpable Arterial Coats in Children Dr. A. E. Vipond, of Montreal, states that during the past year he has met with several examples of arterial thickening in children as a familial condition and of non-syphilitic origin. In a number of cases the children were thin and undersized. The left ventricle was not hypertrophied, the blood pressure was normal, or might be slightly raised. The occurrence of nephritis was accidental. No symptoms were present, and the condition did not shorten life, so that its discovery was often only accidental.—Dr. D. J. Hishon reports a case of Measles complicated by Gangrene of the Legs, with comments by Dr. J. D. Rolleston, who has collected 11 other cases from the literature since 1782. Although gangrene of the extremities as a sequel of an acute infectious disease is usually attributed to autochthonous thrombosis due to acute arteritis, in the present case the origin of the gangrene was undoubtedly embolic, in view of a definite cardiac lesion and an infarct in the kidney found at the necropsy. The abstracts from current literature are devoted to alimentary diseases.

# New Inventions.

## AN IMPROVED FORM OF LUMBAR PUNCTURE NEEDLE.

ACUTELY ill and unconscious patients cannot be placed in the position most suitable for lumbar puncture. It frequently happens in such cases that, when the needle has entered the spinal canal, the cerebrospinal fluid, instead of dropping free from the needle opening, runs back along the outside of the shaft. It is thus difficult to collect and a quantity is lost. In the modification shown a small outlet pipe is fitted near the end of the needle. When the latter is in situ the stilette is withdrawn to just beyond the inner opening of the small outlet pipe, through which the cerebro-spinal fluid escapes. It is easily collected, and by means of the stilette the rate of flow can be regulated.



The improved needle, which has been successfully used in many cases and has proved of much practical value, is made by Messrs. Allen and Hanburys, London.

These notes are given with the approval of the Director-General, Medical Department of the Admiralty.

W. I. GERRARD,
Surg. Lieut.-Comdr., R.N.

A CENTURY OF HONORARY SERVICE.—Dr. F. R. Mallett has been presented by the committee and honorary staff with a silver salver and a gold cigarette case in recognition of the remarkable circumstance that his grandfather, his father, and himself have been honorary surgeons of Bolton Infirmary since 1826. Dr. Mallett was appointed in 1893, and Dr. R. D. Mothersole, his senior colleague on the honorary staff, described the occasion as "unprecedented in medical history."

## JBLIC HEALTH.

is set out recently in a the Minister of Health which the public may be, structed in health matters. s that public health educaial and propagandist, the ofessorial function and the xperts, the latter being the by qualified persons of the nstructed experience. Both recent meeting of the Royal rof. E. W. HOPE invited his o study of the influence of the e advancement of the public hole-time professorial chair of d, was founded at Edinburgh in which date Glasgow and Cardiff while London, he presumed, lar happy position within a short no meeting Sir W. MACPHERSON m for the Army Medical School to -time professor of hygiene before ould boast one, in the person of , whose "Manual of Hygiene," 5, was the earliest comprehensive bject. The policy of present-day ts is increasingly directed to education with a view to the spread of sound edge which remains in the possession hat extent sterile, and some of the recognising the vital importance of hose official duties will bring them with the people and whose duty it date established facts for the public hich will make their application com d welcome. In this discussion Sir NAN, speaking along similar lines, loser relation between the practical he University. Certainly much may the training of sanitary inspectors, and other members of municipal staffs schools of social science or public ool perhaps has been more alive to any other University city, and the seen in a keenness for hygiene which h, where certainly much was needed, lated other communities to like effort. nal side of public health education is a mandated territory by the Society of rs of Health.

One a

ficially

consic

andist side of public health education difficulty that what is the business of ble to perform it may become the busi- or get performed by those without due GEORGE NEWMAN in his Memorandum ganda as concerted movement for the of a particular doctrine or practice, and f it, which is that of all true missionary rell expressed in a recent letter from LODGE to *Nature*, which concludes: "I will not refrain from stating what I firmly conceive to be the truth, as demonstrated by clear and repeated evidence, whenever such statement seems called for. If I had any uncertainty about it I would say so, but it is madness to be false to truth—no matter what the penalty may be." Those responsible for the New Health Society, feeling the responsibilities which have been assumed by their propagandist body, will be expected to scrutinise carefully the bearing and form of their utterances. In the *Medical Officer* of March 27th the honorary medical secretary of the New Health Society defined the truth which the Society exists to impress—namely, that "some of the influences which have come into play with civilisation, such as that of the unfavourable change in the habits of food with the resultant extra intestinal disease and faulty nutrition can be best countered by a return, in some measure, to the habits of food and bowel evacuation of primitive man"; and he adds, "this teaching is based on the unassailable excellence of scientific work of the last 20 years as to the intimate connexion between diet, constipation, disease of the gastro-intestinal tract and the resistance of the body to disease." Throughout the third number of the Society's *Bulletin* for March, 1926, this central aim is set forth many times in different words. People are adjured to give up factory-made foods and drinks, to discard "unnatural pseudo-scientific stuff," not to consume sugar, which is "the deadest of dead foods," to eat slowly and so "do with much less food." Constipation being regarded as the curse of civilisation, "those who eat three meals daily should get rid of waste matters thrice daily," and we should return to the habit of tribesmen whose bowels act three or four times daily and whose motions are soft. Primitive man exercises his abdominal muscles by dances which involve crouching and hopping, and the *Bulletin* reiterates the need for culture of the abdomen in the modern world. Those who wish to avoid appendicitis are exhorted to "shun artificial, manipulated foods." There is no actual statement in the text of the *Bulletin* that cancer will thereby be avoided, although an advertisement has been admitted to a prominent place which states that a form of cooking utensil will "cure constipation and prevent cancer." Do the utterances of the Society, which will have much lay acceptation, conform to medical experience? And do they represent fully the objects which public health propaganda should have?

TH

With some of the teaching to be found in the *Bulletin* all medical men will agree, but many will find that distorted values have been put upon general tenets, and some will consider that there are scientific reasons for holding contrary views. This is inconvenient when public propaganda is employed in dealing with medical questions, because the audience addressed cannot be expected to know the value of the evidence upon which the general views are founded. But supposing that the scientific information which is being placed by the New Health Society at the disposal of the public was unchallengeable, there would still remain need for an explanation of the monotony of that teaching. Faulty feeding, whose connexion with the incidence of cancer is not known to exist at all, cannot be claimed as a universal cause or excitant of all lapses from health, and it is to be hoped that the Society will direct the attention of the public to other places than the dinner-table for examples of the failure to maintain hygienic standards, with the pathological sequelæ. And with regard to that aspect of health to which as yet the New Health Society is confining

---

f Health. Public Education in Health. Revised, Stationery Office. 6d.

its attention, it may be pointed out that there is room for much more scientific endeavour on the lines suggested by Sir GEORGE BUCHANAN, when advocating a firmer liaison between academic teaching and practical work in hygiene. Certain of the views put forward by the *Bulletin* would have far greater appeal to medical men and would be more satisfactory to lay audiences if research work along the usual lines were being carried on in support of this teaching. There is too much loose talk among the public in the course of which all sorts of diseases, especially malignant conditions, are stated to have their origin in all sorts of things, especially food. But there is too little public appreciation of what is meant by scientific evidence, and what methods can be taken to elicit scientific truth. It may lie in the hands of the New Health Society to do much good here by future propaganda.

◆

## THE SITUATION OF THE VOLUNTARY HOSPITALS.

DURING the last few weeks a large number of voluntary hospitals have issued their reports and held their annual meetings. The circumstances of no two hospitals are ever identical, but these reports and the speeches at the meetings at which they were adopted nevertheless show that in broad outline most of these institutions find themselves in much the same position and faced by similar problems, some of which can only be described as acute. The dominant impression left by the study of a large number of reports is that during the last few years the outlook of the hospitals upon the community and of the community upon the hospitals has entirely altered. Hospitals are no longer charities maintained to a comparatively small extent by "pious founders," but mainly by the benevolent well-to-do for the benefit of the poor. They have become remedial, and occasionally preventive, institutions kept going by a rapidly increasing proportion of the people and used by classes which, not so long ago, would have regarded the occupation of a hospital bed as a slur upon their social status. The reasons for these changes are too familiar to call for elaboration; their occurrence and the conducing factors have been noted regularly in these columns. Growing costs compelled the hospitals to cast a wide net for subscriptions; the working classes quickly realised the overwhelming advantage of acquiring at a cheap rate the right to hospital treatment; the amazing rapidity with which the scientific and research side of hospital work has grown has brought to their doors many patients who, although not weekly wage-earners, are unable to face the cost of special private treatment. The future of the hospitals has thus become everybody's problem.

Broadly speaking, the financial position of the voluntary hospitals, as disclosed by their annual reports, is fairly satisfactory, a position for which our readers have been fully prepared. As a rule they are paying their way, and a certain number have achieved surpluses sometimes astonishing in their novelty. There are still deficits, but they tend to diminish both in amount and in number. This improvement in the pecuniary situation is due mainly to the wide creation and rapid extension of contributory funds, which have not only greatly multiplied the number of supporters but provided the hospitals with a steady and increasing income. There is solid reason to hope that as these funds become omnipresent they will obviate the necessity for the frenzied special appeals which do so little credit to our business instinct and form so woefully insecure a foundation for the cost of curative work and steady and methodical scientific research. To secure this consummation, however, these funds will have to be extended very widely, since it is certain that expenditure will increase heavily as the hospitals become more and more centres of research and laboratory investigation, and approximate more closely to the ideal of prevention. Many years must elapse before we can save on the cost of cure enough to pay for the cost of prevention. Another principal reason for the present and future growth of expenditure is the necessity which faces the majority of hospitals for large extensions. On every hand there is a cry for more wards, larger out-patients' departments, more scientific apparatus and therapeutic appliances, more convalescent homes. Patients, both in and out, have increased with extraordinary rapidity of late. Some of the great hospitals see their out-patients growing by thousands, while lists of patients waiting for beds which, even after the careful sifting which they admittedly require, reach pitiful dimensions. There is nothing more harrowing to the medical staff of a hospital than the knowledge that delay in admission means that slight cases become serious and serious ones incurable. Another tax which has lately been put upon already overstrained resources comes from the alarming increase in traffic accidents.[1] Last year, according to a Home Office return just issued, there were more than 115,000 such accidents, 3525 of which were fatal. Urgent casualties cannot be relegated to a waiting list, and by no means all of these motor mischances can be dealt with in the out-patients' department.

Necessary extensions are, then, the most serious problem with which the voluntary hospitals at present have to deal. Government help has been refused, possibly unwisely, and very few institutions can hope to save anything tangible from their current revenue. For the cost of extensions the hospitals have to look to special efforts, to exceptional individual generosity, or to large legacies, and probably the special effort is at present the most fruitful source. The help that might conceivably be obtained by a change in the Poor-law which altered the status of the "infirmaries" run by the guardians is highly uncertain, and in the main it is clear that the voluntary hospitals will have to work out their own salvation. Their board rooms are full of courage and confidence, but the burden will have to be shouldered by the entire community, which needs to learn more completely than it has at present that the hospital problem is a national one and can only be solved by the nation acting as a huge sodality and for its own exceeding great advantage. The need for extensions is sharpened by the desirability, generally felt, of making some provision for patients who can pay reasonably for their maintenance and their medical care and a moderate surgeon's fee. There are no very brilliant prospects of profit in this direction when the cost of providing accommodation is allowed for, but there is a clear advantage in a small proportion of patients who not only cost nothing, but make some contribution to the funds. Already there is a notable increase in payments received from ordinary patients, though it is generally observed that the gratitude of persons cured of the hurts received in motor accidents rarely takes a tangible form, even when they recover compensation from insurance companies.

---

[1] In the House of Commons just before the Easter recess Sir Herbert Nield asked the Prime Minister whether, having regard to the heavy charge which fell upon the voluntary hospitals consequent on the reception and treatment of persons injured in road accidents, who in many cases were non-resident, and whose injuries were frequently caused by reckless driving or at excessive speed, and to the fact that the injured persons were generally unable to make any contribution towards the cost of their treatment, he would consider the desirability of amending the law by enabling the court, upon a conviction of an offender, to include in the order the payment of a fixed sum, by way of contribution, to the hospital or authorise the payment out of the fines levied by way of penalty for motor offences a lump sum, or by way of percentage, to the hospital rendering aid in these cases as the court of petty or quarter sessions might direct, or to be paid out of the general fine fund of the court.

He also asked whether fines imposed upon persons convicted of reckless driving of motor-cars or at an excessive speed amounted to a considerable sum; and, having regard to the fact that during the year 1925 the sum so levied by the Ealing section of the Brentford petty sessional bench and actually recovered for fines amounted to £783, and that during the same period the King Edward Memorial Hospital, Ealing, expended approximately £1190 in treating patients injured in motor accidents within the borough over and above contributions received from patients, and that such results were probably the same in other places, he could see his way to promote legislation which would authorise the making of grants to hospitals treating such patients out of the fine fund of the courts imposing such fines.

Colonel W. Ashley (Minister of Transport) replied: I will bear in mind the suggestion, but I cannot hold out any hope that it will be possible to introduce legislation to give effect to it.

The past year was remarkable for the extent to which "wireless" was introduced into hospitals. Very many of them now possess "radio," and within a comparatively short time this diversion will probably be enjoyed by all of them. We note with satisfaction the dying struggles of the antiquated and thoroughly objectionable "ticket system." A minority of benevolent but old-fashioned people cling to it still, but it is doomed, and few tears will be shed over its tomb. It belongs to the old conception of the hospital when a few guineas bought a certain amount of patronage, and the hunt for tickets was often an exasperating preliminary to admission. To sum up the experience of the past year it may be said that the outstanding fact on the financial side is the rapid growth in contributory schemes and in their product. They are now the biggest source of revenue, and during the last five years have increased on the average 10 per cent. every year. On the scientific side we see an equally rapid growth in the use of X ray and sunlight treatment, and electromedical helps generally. There has also been an exceedingly promising quickening of interest in orthopædics, the far-reaching importance of which is beginning to be more definitely understood by the general public. There is reason to be thankful for anything which focuses lay attention upon the grave fact that a vast proportion of the physical suffering of mankind is the direct result of the neglect of disease and deformity in the early stages.

◆

## THE USE OF PSYCHOTHERAPY.

WE commented a fortnight ago on the prominence assigned to psychotherapy by Dr. FARQUHAR BUZZARD in his recent Lettsomian lectures, pointing out that, if psychotherapy is as indispensable as it is claimed to be, the principles governing its employment should be far more widely recognised and systematised than they are. It was further suggested that this lack of recognition and of system could be traced to a profound disagreement among psychotherapists themselves as to the choice of methods and of patients, and also to an absence of information regarding the results obtained by recourse to these various procedures. With respect to the latter the annual report[1] of the Medical Director of the Cassel Hospital for Nervous Disorders contains a great deal of valuable and practical information on what is admittedly a difficult subject expressed in language which all can understand. Two aspects of the report call for consideration. In the first place Dr. T. A. Ross has set out to demonstrate that "illnesses or states of discomfort of purely psychogenetic origin exist, which have no ætiological relations with the body, and which can be abolished by a change of mental orientation." To some it might appear unnecessary to labour this point, for common sense, embodying as it does the wisdom of the ages, surely teaches us that abnormal states of mind may and do arise independently of any physical disorder. Dr. Ross, however, very properly points out that while no one would deny that psychical symptoms may be directly dependent on toxic or chemical causes, there have recently been, especially in this country, clear indications of a return to the belief that physical conditions are usually at the bottom of all mental disorders, including that type of mental disturbance most commonly found in patients admitted to the Cassel Hospital—namely, anxiety states.

By the aid of case material the psychogenetic origin of symptoms is lucidly explained, beginning with quite simple examples and proceeding to more complicated ones. A study of these cases would seem to provide convincing demonstration of the correctness of the hypothesis which it is the object to prove. The fact that the hypothesis is independent of phenomenal reality is immaterial, provided that, as Dr. BERNARD HART has recently pointed out in his Goulstonian lectures, it explains the observed facts, is not contradicted by other facts, and is capable of verification by repeated reference to experience and experiment. It must also be borne in mind that in many of the patients the psychogenetic nature of their symptoms had not been recognised prior to their admission, while most of them had been previously submitted to physical treatment which had failed to cure them and in many cases had made them worse. From the practical point of view the crux of the matter would seem to lie in the necessity of recognising that symptoms may arise independently of bodily disease, for it is obvious that unless their psychogenetic origin is admitted, the question of dealing with them along psychotherapeutic lines can never arise. The report also refers to the fact that the symptoms complained of are, many of them, or more properly the majority of them, physical in character. This is a matter of some significance, for it is perhaps natural to assume, and the general tendency of medical teaching has always tended to support the assumption, that all bodily disturbances have a physical basis. It is much easier for the student of medicine to believe that indigestion and palpitation are the result of some subtle changes in the gastric mucosa and myocardium respectively than to be convinced that they may be the bodily expressions of some disordered state of mind. Moreover, once such convictions have become generally established many chapters of our medical text-books will have to be rewritten. In this connexion it is worth recalling that psychopathology has mainly grown from the investigation of hysteria in which the phenomena are in great part physical in their manifestations.

The second aspect of the report concerns methods of treatment and the results of treatment. Dr. Ross gives concrete examples of the several methods of psychotherapeutic approach. Where the nature of the anxiety is recognised by the patient or is revealed by the history of the illness, evaluation of the symptoms is often sufficient to secure the necessary relief, but the explanation given by the physician must fit the history and be positive in character, that is to say, the symptoms must be accounted for "in a fashion which really makes their presence a thing that might have been expected." This procedure, which is relatively easy, is suitable for those simpler forms of neurosis in which emotional reactions produced by anxieties and conflicts have been misinterpreted by the patient and regarded as signs of physical disease. The positive explanation, it may be noted, is the very antithesis of that which is too often given—namely, that "there is nothing the matter." In certain cases where the anxiety or conflict is not on the surface Dr. Ross considers that the physician is justified in making speculative inferences as to its nature, although he admits that this method is capable of becoming "a haphazard and dangerous procedure." But in those patients who are quite unaware of the causation of their symptoms, and where no grounds exist for speculative inference, recourse must be had to the method of free association or to hypnosis, and a very interesting example is given where these two methods were employed together successfully. Of the 114 patients suffering from one or other of the psychoneuroses, who were discharged during 1924, 86 were well or much improved, and although out of these 86 there were some "whose difficulties seemed to depend on complexes which were unconscious in the Freudian sense, complexes which when they were discovered struck the patients themselves as very important," the majority were probably assisted to recovery by simple explanations and the discussion of difficulties of which they were for the most part aware. Herein seems to lie a feature of great practical significance, especially when taken in conjunction with the good reports obtained from patients discharged in previous years, reports which pay tribute to the efficacy of the treatment and to the value of an efficient follow-up system. For it may fairly be submitted that the type of case which is treated successfully at the Cassel Hospital is in no way peculiar to that hospital, but abounds in every class of practice. Of the total admissions 75 per cent. suffered from one or other of the psychoneuroses, and of these a large majority were relieved or cured by methods which are sufficiently simple and straightforward as to be within the reach of any doctor who wishes to make use of them. It is often stated that these methods take more time than the general practitioner can afford, but this is largely a fallacy, for very many cases take up no more time than is spent over many physical illnesses. What, however, does take time is the initial physical examination which cannot be too thorough, and the taking of the history which cannot be too detailed. Unfortunately it can hardly be denied that the prime importance of accurate history-taking is not sufficiently emphasised in our medical schools, although in all disorders, both of mind and body, it ranks easily first as a method of investigation. It is not enough for the patient to enumerate his or her symptoms; the physician must acquaint himself with the order in which they appeared and with the circumstances in which they appeared, and it is the latter especially which so often provides the clue to some emotional stress of the existence of which the patient may be aware, but the effects of which he has ignored or misinterpreted. Without an accurate history no diagnosis is possible, and diagnosis is as essential a precursor of rational therapy in disorders of the mind as it is in disorders of the body.

---

[1] Obtainable from the Medical Director, Cassel Hospital for Functional Nervous Disorders, Swaylands, Penshurst, Kent.

The report briefly discusses the Freudian view that for the purpose of curing a psychoneurosis it is necessary in every case to go to the ultimate cause. Dr. Ross's experience is to the effect that this view is not necessarily true, for the reason, if we have not misunderstood him, that he so often finds that the anxiety is within the patient's consciousness and deeper excavations are therefore not indicated. Where, however, the problem is obscure he raises no objection to the method of free association or of talking at large, provided due care is taken "not to strain associations or to force them upon the patients," a precaution which seems to us eminently sound. From the next report we hope to learn more as to which types of neurosis are particularly amenable to treatment and which are most resistant. Consideration of this valuable document compels us to revert to the plea we put forward a short time ago for the greater systematisation of psychotherapeutic principles. It would be well not to forget that, as Dr. W. RIVERS insisted shortly before he died, psychology is a new science, and that owing to premature and over-ambitious attempts to apply its supposed discoveries to practical problems, while the basis upon which they rest is still insecure, there is a serious danger that the science itself may fall into discredit, and that instead of its study receiving almost universal interest it may even become a matter of ridicule. The psychotherapist who claims that there is only one method of treatment, be it hypnosis or auto-suggestion, for every kind of mental illness, is no more and no less ridiculous than the osteopath who claims to cure all bodily ailments by manipulation of the spine, or the physician who prescribes digitalis indiscriminately in all affections of the heart. The application of psychological principles to clinical medicine must be carried out with caution and sobriety, and it is ardently to be hoped that the medical profession will have the good sense to turn a deaf ear to preposterous claims, and will resist the temptation of accepting wholesale attractive hypotheses, which while containing some measure of truth, do not contain the whole truth and nothing but the truth.

◆

## INTERNATIONAL SURGICAL CONGRESS AT ROME.

THE Seventh International Surgical Congress, which has just concluded its sessions at Rome under the presidency of Prof. Giordano, of Venice, was attended by more than 500 surgeons from many European countries and the United States of America. The principal subjects set down for discussion were: (1) Radiotherapy of uterine cancer; (2) Abscess of the liver; (3) Treatment of surgical tumours: (4) Surgery of the spleen; and (5) Remote results of Jacksonian epilepsy, each of which led to lively discussion. The opening of the Congress was marred, as everyone knows, by a deplorable attempt upon the life of Signor Mussolini, who had been present at the inaugural session. By a fortunate chance the Premier had just turned his head to respond to the salutation of the crowd at the moment when the firearm was discharged, and the bullet only caused a shallow wound of the lower surface of the nose. Members of the Congress were witness of the singular courage shown by Signor Mussolini during this ordeal, his first words being an encouragement to those around him to show an example of perfect calm. First aid was rendered by the President of the Congress and Prof. Bastianelli. Signor Cremonese, the Governor of Rome, in a message to the Congress, declared that under the Fascist régime Rome was more than ever desirous to contribute her part to science. The Premier took as his text the original significance of the word surgeon—that is to say, handworker, going on to speak of the surgeon's task as something far more than handiwork, demanding in fact the highest gifts of intelligence and character.

"Ne quid nimis."

## THE OPTICAL CONVENTION.

THE Optical Convention closes at the end of this week, and judging by precedent it will probably be many years before anything of the kind will be held again in this country. We regret this, for the knowledge disseminated is valuable. Those who have visited its exhibition at the Imperial College of Science, South Kensington, will have realised afresh how vital is the science and industry there represented. It is the handmaid of myriad arts and occupations, and it is a servant so efficient that people easily forget the complicated technique which underlies its service. During the greater part of last century, as the Prime Minister pointed out in his opening address on April 12th, British work in the optical industry was predominant, and it was not until the end of the century that it was first threatened, and finally almost overwhelmed, by foreign competition. The grave difficulties of the war decided the Government to safeguard the industry, and a substantial grant was also given to the British Scientific Instrument Research Association. This measure of protection had its critics; but the case for subsidising the optical trade was more convincing than some others, for the competition of countries with depreciated exchanges would have made it difficult, if not impossible, to re-start an industry such as the manufacture of optical glass—which had almost died out in this country—without assistance of some kind from the State. At South Kensington there is an interesting display of the optical glass now being produced of which there are over 100 varieties. This is one of frequent exhibits of general interest, but there are also many which are likely to interest medical men especially. Innumerable kinds of ophthalmoscope are shown, and there are many beautiful drawings of abnormal conditions of the fundus. The Refraction Hospital and many private firms exhibit in profusion the latest apparatus for the practice of ophthalmology, and specialists will do well to avail themselves of the opportunity for comparison afforded. Needless to say, there is an excellent display of microscopes, and not the least interesting is the collection of early models, many of which were used by famous scientists of the seventeenth and eighteenth centuries. Demonstrations of some of the more celebrated experiments in the history of optics are given. To mention the other sections of the exhibition would savour of the catalogue; all that is needed is to say that nothing seems to be missing to make it complete within the wide bounds laid down. The visitor may be tempted at first to spend his time in seeing the sideshows and in cultivating his capacity for being deluded. But he will soon find that the rest of the exhibition is even more entertaining than the entertainments, besides being instructive even to the ignorant.

## IONIC MEDICATION IN DENTISTRY.

THE theory underlying ionic medication was strongly attacked some years ago by Dr. David Campbell,[1] who claimed that the amount of any drug which could be introduced was so negligible that the method offered no advantage over administration of the same drug by the mouth, by inunction, or by hypodermic injection. He also stated that there was no evidence of local concentration or deep penetration, and that any good effects were due to the electric current rather than to the drugs used in connexion with it. Mr. Owen Morphy, in a thoughtful paper which recently appeared in the *British Dental Journal*,[2] carefully analyses Dr. Campbell's criticism, and contends that ionic medication is both theoretically and practically justified as a method of securing a greater penetration of drugs than is possible by other forms of application. He discusses its use, especially from the dentist's point of view, and in dentistry the conditions are in some ways special. As he points out, inunction and hypodermic medication are not possible in the treatment of pyorrhœa or sepsis of root canals, the two chief dental conditions in which ionic medication is employed. He lays stress on the fact that the ionised drug is in a nascent form, and there is strong evidence, he says, that various drugs are more potent in this form. Dr. Campbell carried out a series of experiments to show that when a drug is introduced into the body by ionic medication, it passes so rapidly through the tissues, as estimated by its appearance in the urine, that any great amount of local concentration is unlikely. He also considered that its rapid appearance in distant parts of the body was an argument against any deep local penetration, since the ions give up their function of carrying the current almost immediately they pass the skin. But even in Dr. Campbell's figures for iodine there was a margin of 20 to 40 per cent. of iodine unaccounted for; and Mr. Morphy suggests that, conceivably, this represents in part the iodine which has been introduced into the tissue cells and temporarily fixed there. It is noteworthy that in Dr. Campbell's experiments the amount of iodine present in the urine increased with the strength of the current employed. In dentistry only weak currents are used in ionic medication. While it may be granted that the actual amount of iodine ions liberated is small when used in root canal work or in the treatment of pyorrhœa, Mr. Morphy rightly says that even a small amount of so powerful a drug as nascent iodine may not be negligible when introduced into the narrow space around the apex of a tooth or into the narrow zone of tissue in a pyorrhœa pocket. The only alternative to ionic medication, moreover, is the local application of a drug under conditions which do not readily favour its penetration to the actual area of infection. Apart from the particular conditions existing in the mouth, Mr. Morphy questions whether hypodermic injection gives as much local concentration as ionisation. In local analgesia, in order to obtain a local concentration of the anæsthetic, it is necessary to add adrenalin to prevent a too rapid diffusion which would defeat the ends for which the anæsthetic is given. An argument advanced against deep penetration is that, according to experiment, ions cannot be driven through the skin to a greater depth than the subcutaneous tissues, owing to the resistance of the skin. Mr. Morphy concedes this, but points out that in pyorrhœa the pocket has largely lost the normal lining of epithelium present in the gingival trough. Similarly, in root canal treatment the apical tissues have no epithelial lining; there is no cutaneous resistance to limit the penetration of ions into the submucous tissues. He reproduces two microphotographs taken by Mr. E. Sturridge showing very definitely the amount of penetration possible through the gum of a living animal. The argument that the good effects of ionisation are due to increased generation of heat does not really affect the use of ionic medication in dentistry. The simple ways of applying heat used in other parts of the body are generally not appropriate to the treatment of the dental tissues, and although it is quite possible that some of the good results of ionic medication may be due to heat, this fact in no way detracts from the value of the treatment for dental conditions. Again, the argument that ionic medication acts by producing hyperæmia, while affecting the validity of the underlying theory of its action, is no argument against its practice, especially in the treatment of pyorrhœa or septic root canals. As Mr. Morphy points out, such views only bring ionic medication closer into line with high frequency or ultra-violet radiation in the treatment of dental disease. He lays a good deal of stress on the coagulating power of zinc ions. In root canal therapy this tends to promote dryness of the apical region which is so difficult of access. The coagulation, he suggests, may be beneficial in the treatment of pyorrhœa by sealing and sterilising the suppurating surface of a pyorrhœa pocket. On clinical grounds there seems little doubt that ionic medication has a beneficial effect in the treatment of pyorrhœa, especially in the early stages of the disease. Pyorrhœa is so notoriously difficult to treat that it is far from easy to evaluate the many forms of treatment employed. Ionic medication will not work wonders, but used judiciously in combination with other methods it has a definite place in dental therapeutics. Its exact mode of action remains uncertain, but Mr. Morphy's views are reassuring to those who use this form of treatment in dental conditions, and consider it both legitimate and valuable. That part of its action may be due to increased heat and a local hyperæmia may well be true; but, if so, this is an added argument for its use.

## FLYING DOCTORS.

The distinguished specialist who flies once in a while to a rich, importunate, and distant patient is already familiar to most of us. Less is known of the systematic use of aeroplanes for the sick and injured, although the ambulance aeroplane has already done good service. It was first used by the French Army in Morocco under Marshal Lyautey. In May, 1921, 20 aeroplanes, each carrying two stretchers, were sent to Morocco, and proved so successful in evacuating the wounded that since then many more have been employed. The Swedish Red Cross has done pioneer work in using an ambulance aeroplane to transport the sick from its sparsely populated northern areas to the nearest hospital, often over 100 miles distant. In 1923 it applied to the Government for a subsidy to purchase an aeroplane for this purpose, and the Government agreed to share the expense of purchase. The machine is piloted by military airmen, and the Red Cross defrays the running expenses. Many lives have been saved by this means. One patient, suffering from hæmorrhage and living in a very isolated part, was transported in an hour and a half to the nearest hospital at Boden, whither the journey by sledge would have taken at least 20 hours. Once the idea had taken root its corollary became evident. If an aeroplane can take the patient to the doctor it can also take the doctor to the patient. This second life-saving use for the aeroplane is particularly applicable to Australia, with its average population density of only 1·83 persons per square mile, and in the April number of *The World's Health* H. C. Loeffler tells how the aeroplane is helping to solve the problem of providing medical aid to distant settlers in that country. A single doctor at Darwin has a practice extending over an area ten times that of Great Britain, but the condition of roads and absence of bridges no longer prevent him from reaching patients far off in the Bush. The Australian Inland Mission, which has already been instrumental in supplying nursing homes to the "Outer Bush," is now proposing to extend its activities to supplying doctors by aeroplane. It has therefore mapped the central part of the continent into circular districts, each with a radius of 200 miles which could be covered by flying doctors when necessary. As a first step, the Mission proposes to develop a wireless service and to educate bushmen in its use. Meanwhile the aeroplane plan has been submitted to the National Commission on Health, and it is hoped that it will meet with this body's approval. The plan includes utilisation of the regular mail aeroplane services to furnish personnel and equipment, under contract, for carrying these flying doctors.

In England communications are so rapid and distances so short that little use has been made of aeroplanes for medical purposes in civil life; but in the United States, if ordinary means of transport fail, the Red Cross can call on the aeroplanes of the Army, the Navy, and the Postal Services to send help to the victims of distant railway accidents, mine explosions, and epidemics. Outbreaks of diphtheria in remote districts have been dealt with effectually by sending doctors, nurses, and serum in a few hours instead of days. Aviation has also helped in the prevention of disease; for in Louisiana aeroplanes have been used to destroy mosquito larvæ by spreading Paris green over the surface of large lakes. All over the world there are rescues and reliefs recorded which recall adventures told by writers in boys' books which seemed fantastic two or three decades ago. In Switzerland an aviator dropped food down to a party cut off on a mountain side; in Sweden some fishermen were saved from starving on an island when their communications were cut off by the breaking of an ice bridge; in Nigeria the wife of a British official was bitten by a mad dog and—by courtesy of the Governor of French West Africa, who sent her an aeroplane—was transported 1300 miles to the Pasteur Institute at Dakar, which she could not otherwise have reached for a month. The aeroplane, it is evident, has its record of salvation as well as of destruction, and in the face of so rapid an advance it is not surprising to learn that in Columbia (South America) a hospital is being built with a flat roof on which, it is hoped, the regular air ambulances will alight with their cargo.

## ARSENIC IN APPLES.

At the end of last year several Hampstead tradesmen were prosecuted for selling Jonathan apples which contained sufficient arsenic to have given rise to complaint of illness on the part of some who had eaten freely of them, and it is now stated on behalf of retail fruiterers that the public are to some extent neglecting apples and purchasing other fruits instead. This would be unfortunate, for, as we pointed out in commenting on the Hampstead prosecutions, the apple is a delightful and important article of food, and there is a large trade in this fruit between this country and America. The *Literary Digest* of New York for Feb. 20th reproduces our annotation of Dec. 19th, 1925 (p. 1295) substantially in full, and this has led Mr. J. H. Merrill, Ph.D., in charge of fruit insect investigation at the Kansas State Agricultural College, to protest in a letter to the Editor of the *Digest* against what he describes as the most ill-informed article he has ever read in any publication, adding, "the ignorance displayed in it hits at the very foundation of one of the great industries of the country, that is, fruit and vegetable growing." Dr. Merrill admits that "some physician may have found arsenic in apples," but he asks us to take into account the number of people that have eaten apples from sprayed trees without being injured in the least. "When you consider how many of them are still living," he writes, "you will admit that the mortality rate from eating arsenically-treated apples is remarkably low." We can agree with Dr. Merrill that arsenical poisoning from consuming apples may be uncommon, without sharing his view that the event is unimportant when it does occur. It has occurred precisely as we said, and we are glad to have drawn attention to the occurrence. The material part of Dr. Merrill's letter, however, is his statement that the arsenic found in apples comes from the soil in which they are grown rather than from the spraying. This fact, he says, was brought out at a meeting of the American Association of Economic Entomologists held in Boston in December, 1910, where it was shown that when apple-trees are grown in soil which contains arsenic, the arsenic may be recovered from the wood of the tree and the fruit. This possible provenance of the arsenic found on analysis deserves investigation, but the information is not new. A certain amount of evidence has been available in this country for more than 20 years. Experiments were conducted at the Woburn Experimental Farm in 1901 by Mr. J. A. Voelcker, Ph.D., on behalf of the Royal Commission on Arsenical Poisoning, to see whether ordinary farm crops took up arsenic either from manures in which it might occur or when arsenic was added direct to the soil. The work was conducted on barley and on swedes, and Dr. Voelcker found[1] that arsenic did not enter into the matured grain of the corn crop nor into the bulb of the root crop, although it might be found in the green leaves of the swedes and in the green stalks of the corn crop if cut early. These results confirm the contention of Dr. H. E. Cox, public analyst for Hampstead, that arsenic is not natural to apples, and, as Dr. Cox remarked in an article in the *Analyst*, to which we have already drawn attention,[2] the presence of lead with arsenic in or on apples is fairly conclusive evidence as to its source. We must provisionally regard as a possibility the finding of appreciable quantities of arsenic on the peel of apples which have been sprayed with it after the blossoming period, but we hope it may be possible for the appropriate Ministries in apple-growing and exporting countries to take measures to reassure the public of the practical freedom from arsenic of apples intended to be consumed in a raw condition. The Association of Apple-growers in Nova Scotia has, we understand, appointed a committee to investigate and report.

## A TUBERCULOSIS MATERNITY CLINIC.

FOR the last six years Prof. A. Couvelaire has been running a special service[3] at the Clinique Baudelocque, in Paris, for the care of pregnant women suffering from pulmonary tuberculosis, with the express object of protecting their new-born babies from maternal infection. This service is run in connexion with various antituberculosis dispensaries and with those organisations which board out the children of tuberculous parents in foster homes, according to Grancher's principles. A special pavilion at the clinic has been set apart for confinements, and each mother has a separate room. Those who are already receiving treatment for tuberculosis can continue their treatment during their lying-in, and as soon as a child is born it is separated from its mother and is put in a special ward in another pavilion. As soon as it has been established, by medical examination at the clinic, that an expectant mother is tuberculous, she is referred to one or other of the specially equipped tuberculosis dispensaries, usually the Léon Bourgeois Dispensary, where arrangements can be made at once for the ultimate boarding out of her child. When the mother comes out of hospital after her confinement, she is again referred to the dispensary for advice and treatment. The babies are removed from the hospital as soon as possible—that is, as soon as artificial feeding has been properly established and the weight curve is satisfactory. They are taken straight to their foster home in some country district, and here they stay until they are at least 4 years old. The organisation of the service has been made possible only through the competent help of a trained social worker, who obtains all the family and social histories. From November, 1921, till October, 1925, 231 infectious tuberculous cases were confined in this small annexe; 13 of them died under care, two from obstetrical complications, and 11 from tuberculosis. Of the 101 women who entered the clinic before May, 1924, and who were kept under observation during the year after their confinement, 16 died in the three months following confinement, and 23 died between the fourth and twelfth month after it, so that only 63 survived at the end of one year. Of the total of 231 cases, 40 were receiving artificial pneumothorax treatment. None of these had any complications during their confinement. The average weight of the babies born alive was slightly below the normal. Of the 223, three died from obstetrical complications at birth, two from fatal deformities, and four from congenital syphilis; five were born prematurely and survived only a short time. This left 200 survivors, a proportion very little inferior to that observed in most of the Paris lying-in hospitals. Two series of observations have been made by Prof. Couvelaire on the subsequent fate of these children. In 1923 a group of 57 babies placed in foster homes was followed up. Nineteen of them had died before the end of the first month, and one more, kept in hospital because it was delicate, had died at the end of the fourth month. Four of them were born prematurely, but the remaining 16 appeared to be healthy at birth. Out of a second group of 161 babies who showed no signs of tuberculosis, 20 died during the first month and six between the second and third. Prof. Couvelaire's conclusion is that the principal cause of mortality amongst these children is not any weakness at birth due to maternal infection, but is rather the separation and lack of breast feeding. He points out that although the number of children saved by his service is disappointingly small at present, the quality of the survivors has been much improved and many have been saved from tuberculosis.

## THE DEVELOPMENT OF PHARMACY: SIR WILLIAM GLYN-JONES.

Sir William Glyn-Jones has resigned the office of Secretary and Registrar of the Pharmaceutical Society, which he has held for the past eight years, in order to take up the position of Chairman of Council of the newly formed Proprietary Articles Trade Association of Canada, and the Dominions could have found no one more capable to reorganise the business conditions of pharmacy. He first came into public view some 30 years ago as founder of an association to put down certain abuses in the trade of patent medicines which were oppressing the best sort of retail chemists. At that time the sale of some obviously quack nostrums were used by the less scrupulous druggists to attract customers to their shops, the articles being sold at prices which yielded no profit. Consequently, dispensing chemists who did not resort to advertising methods of this kind experienced a falling off in their legitimate business. The new association put a stop to the evil by bringing manufacturers, wholesale druggists and retail chemists together, with the result that regulations were made by which no proprietary medicine, the makers of which belonged to the association, could be sold below a fixed minimum price; any retailer who violated the rules was placed on a "stop list" and prevented from obtaining further supplies of any of the "protected" articles. The economics of this arrangement are not our concern, but it is well that doctors and the public should understand their fundamental object. By bringing together the members of all sections of the drug trade, Sir William Glyn-Jones showed that what pharmacy had long been looking for—namely, an organised plan of development—had been found. Those who saw in the movement nothing but a plan for securing to chemists a profit on proprietary medicines should appreciate now that the outcome has undoubtedly been for the public benefit. Sir William Glyn-Jones may have secured his dominant position in pharmacy by reaching the hearts of men in an obvious way, but he has used that position for very worthy motives; for instance, the formation of the Chemists' Defence Association, the severance from the Pharmaceutical Society's activities of the trading interests of pharmacy, the union of the Society with the British Pharmaceutical Society, and last but by no means least the establishment of the pharmacological laboratories. We have no doubt that in Canada Sir William Glyn-Jones will further prove himself the champion of pharmacy. When Member of Parliament for Stepney he took an active part in the framing of shop hours legislation; he served his craft manfully, sometimes in opposition to the medical view, when the National Health Insurance Acts were in the making; and, as an expert on poison and pharmacy law, he influenced legislation in the Dangerous Drugs Acts. The retail pharmaceutical trade of Canada has selected for its principal executive officer a man with first-class claims for the post.

## THE MEDICAL REGISTER FOR 1926.

ATTENTION has been already called in our columns[1] to certain errors which had crept into Tables (D) and (E) in the newly issued Medical Register for 1926. The pages on which these tables appear have now been reprinted and issued in corrected form to all of those to whom official copies of the Register had been sent. Table (D) as corrected is as follows :—

TABLE (D), *showing the Total Numbers, with percentages of the Whole, of Persons (a) registered in, and (b) remaining in, the three respective " Local Registers " for England, Scotland, Ireland.**

| Country. | (*a*) Total number and percentage of persons registered from the beginning of registration in 1858, up to Jan. 1st, 1926. | | (*b*) Number of persons now remaining in the Register, whose names are contained in the present " Medical Register " for 1926. | |
|---|---|---|---|---|
| | Number. | Percentage of the whole. | Number. | Percentage of the whole. |
| In England .. | 54,192 | 55·13 | 24,842 | 48·01 |
| In Scotland .. | 25,741 | 26·18 | 16,349 | 31·60 |
| In Ireland .. | 15,061 | 15·32 | 7,604 | 14·70 |
| Colonial .. .. | 3,087 | 3·14 | 2,822 | 5·46 |
| Foreign .. .. | 229 | 0·23 | 121 | 0·23 |
| Totals .. | 98,310 | 100·00 | 51,738 | 100·00 |

* The "Medical Register," as formed pursuant to Section XXVII. of the Medical Act (1858), is the aggregate of the three "Local Registers."

The corrected total of persons whose names are contained in the Register for 1926—namely, 51,738—should now be carried forward to the last column of Table (E). In this table two other figures opposite the year 1925 require slight modification—namely, " Number added by Registration : Foreign," should read 9 instead of 8, and " Number added by Registration : Total," should read 2570 instead of 2569. This completes the correction of the 1926 Register, but those who possess the 1925 Register should note that Table (D) in that issue is not trustworthy, and that the total for the year in the last column of Table (E) should read 50,035. It is now possible to infer the increase in registered names during the last two years : there are 1703 more names in the 1926 than in the 1925 Register, and 1895 more names in the 1925 Register than in the 1924—a large increase compared with the decennial average of 851.

Summer Time will commence in Great Britain, Northern Ireland, the Channel Islands, and the Isle of Man next Sunday morning, April 18th, at 2 A.M., when the hands of timepieces and clocks should be advanced an hour. In France and Belgium Summer Time will commence three hours earlier, and according to the *Journal Officiel*, the legal hour should be advanced by 60 minutes at 23 o'clock on Saturday, April 17th. In both countries Summer Time will end on the night of Oct. 2nd/3rd. Summer Time in Holland will not begin until May 15th, and Spain has not yet reached a decision on the matter.

NATION'S HEALTH EXHIBITION AT LEICESTER.—On Thursday, May 20th, at 2.15 P.M., Colonel L. W. Harrison will give an address on the Diagnosis and Treatment of Syphilis, when a film with this title will be displayed. The film has been prepared for the medical profession on behalf of the British Social Hygiene Council, and will be exhibited in the Cinema Hall, Junior Training Halls, Aylestone-road, Leicester. We understand that this film will shortly be shown in the London district. In the same hall at 5 P.M. a conference will be held to consider what further steps can be taken to prevent congenital syphilis, when the opening address will be given by Dr. Norman Cruickshank, followed by Mr. John Adams, Dr. David Lees, Miss Cummins, and others.

## CLXIX.

## THE TREATMENT OF SUBSTERNAL AND PRECORDIAL PAIN.

THE name angina, from its derivation, indicates a breast pang, but in practice has come to mean a heart pain. It is important, therefore, before making a diagnosis of angina to make certain that the pain complained of is a true heart pain. The patient complaining of pain in the region of the heart, or in other parts of the body, often finds it difficult to describe the sensations which are felt. The diagnosis of angina depends in the main on the history which the patient gives. The angina syndrome has certain essential characteristics. The severe pain has a direct relationship to effort, and is only indirectly associated with the taking of food. It may have a close connexion with the emotional state and general health of the individual. The seat of the pain may be localised to one small area in the region of the heart, or may have a widespread distribution involving the chest, neck, jaw, the back, the arms, and the abdomen. It is a continuous pain and is felt in all grades of severity. There may be no signs of structural disease of the heart. In young subjects absence of these signs is exceptional, in elderly subjects frequent. The diagnosis of angina should be made with caution in all young people with structural disease, and rarely if ever when signs of disease are absent. In middle-aged and elderly subjects, particularly in men but not uncommonly in women, the diagnosis of angina will have to be made in many, if not most, instances from the history alone. If angina is understood to be a heart pain, a symptom of myocardial exhaustion—and this is the view generally held, at least in this country—then it follows that a healthy heart muscle can give rise to pain, anginal in character and distribution, when it is called upon to carry a very heavy load. A severe and prolonged exercise can provoke such a pain in a heart that is in no way damaged. The subject of this exercise, if he is in good condition, is less likely to complain of precordial pain or discomfort than another who is in poor condition. An athlete wins a race and feels no pain, but if on another day he is septic half the effort may produce pain of an anginal character. When the myocardium has been damaged by disease, pain may be provoked by severe physical exertion or by the slightest effort, or it may be felt with the patient at rest. Just as some patients complain of breathlessness only when walking up a steep incline, others when walking on the level, or when at rest, so also can patients with angina be graded. The effort required to produce pain should be the index of the degree of myocardial exhaustion. Pain that is felt at rest is therefore comparable with breathlessness at rest, as a symptom of heart failure, but it belongs to a different class. The ease with which pain is produced should be the guide in forecasting the course of the disease. In the same way that breathlessness on exertion may not be due to myocardial disease but to phthisis or some other cause, so also may we expect to find patients with a heart pain due to causes other than myocardial disease.

### *Differential Diagnosis.*

The first object in examining a patient with pain in the substernal area should be to determine whether the pain is due to myocardial disease alone (primary angina), and if so, how far the disease has progressed.

Signs of increase in the size of the heart, with or without valve disease, associated with pain on effort, should be an aid in arriving at a decision in many cases. There will be others without any enlargement of the heart, and with no valve disease; in these myocardial disease may be the cause of the pain. Before this diagnosis has been made, disease in other parts of the body should be excluded. Structural changes capable of undermining the health may cause cardiac pain apart from disease of the heart muscle itself. This is termed secondary angina. A third group of patients with substernal or precordial pain have no signs of structural disease of the heart or any other part of the body. They are classed as neurasthenics. It is a condition most often met with in women, but it may occur in men. In these the diagnosis is made from the absence of structural disease, and from the presence of other symptoms of neurasthenia. Hyperæsthesia over the pain area is more common in this type of case than in primary angina.

If at the end of the examination the patient cannot be placed in any one of the three groups—primary angina, secondary angina, or neurasthenia—then the pain is generally not cardiac at all, but can be accounted for by structural changes or functional disturbance in some organ other than the heart. In some the seat of the trouble lies in the gastro-intestinal tract, perhaps a gastric ulcer or gall-stones; in others the lungs or the pleuræ may be responsible; in not a few cases the genito-urinary tract will be the offending system, with renal colic simulating angina.

### *Appropriate Therapy.*

The treatment of primary angina is that of heart failure. The patient must live within the limits of his exercise tolerance. Those activities, physical or mental, likely to provoke pain must be avoided. In a word, the basis of the treatment in this type of patient is the management of his daily life; a sufficient amount of exercise and no more—all that he can do comfortably without pain. He must be guided therefore in his choice of a suitable occupation, one that does not exhaust or unduly tire the damaged myocardium. The more advanced the disease and the greater the degree of heart failure the more restricted will be the field of cardiac response to effort. Some patients will be complete invalids and bed-ridden; others can do no physical work and are semi-invalids in their daily life; many can over many years do half-time work, and there will be some whose activities are only restricted to the extent of avoiding excesses. The diet should be an easily digested one, erring on the side of low caloric values; small meals slowly eaten, and well masticated, and taken with a minimum of fluid. It is important to rest after meals, for pain is easily provoked at this time. The general laws of hygiene should be rigidly obeyed. Oral sepsis, or sepsis elsewhere, should be removed. These patients do not tolerate cold winds or exposure to dampness. Sleep should be aided by suitable sedatives (bromides and chloral) if there is a tendency to insomnia.

When the anginal attack is severe and persists with the patient at rest amyl nitrite may relieve the pain. Morphia may be required to make the patient comfortable. This drug is well tolerated, and can be given in large doses and repeated. Chloroform inhalations alone relieve some patients of their agonising pain, especially when the anginal attack is caused by thrombosis or embolus in coronary vessels. Sodium nitrite gr. 1, slowly dissolved in the mouth a quarter of an hour before beginning such exercise as walking, may prevent the onset of expected pain. Diuretin given in doses of gr. 10 over a prolonged period is a useful drug. If the patient is of a nervous type, it will be found helpful to add pot. bromide gr. 10 or 15 to the diuretin, and give it in a mixture t.d.s. for a month or longer. Pot. iodide, gr. 10, with pot. bromide, gr. 10, can be given, perhaps with some relief to the patient. In the hypertension cases the iodides are supposed to give the best results. There is no pharmacological evidence to support this view.

With a history of syphilis, or if signs of this disease are present, the treatment should include the usual mercurial treatment with potassium iodide in gr. 10 doses, over a prolonged period. Each year a course of six or eight weekly intravenous injections of N.A.B. 0·6 g. should be given. Diathermy, three treatments a week over a period of a month, is helpful in some cases.

*Surgical Treatment.*—There is no sound reasoning to support the surgical treatment of angina, but there is some evidence that benefit in primary angina has followed the Jonnesco operation of cervical sympathectomy. The results obtained in Vienna by Höfer from cutting the depressor fibres of the vagus need confirmation before this operation can be recommended. Danielopolu has described a modified Jonnesco and Höfer operation the results of which also await confirmation.

*Secondary Angina.*—Here we must rely on removing the primary cause of the disease. The body should be explored for structural disease, sepsis, or some functional derangement; treatment should depend upon the results of this examination. It will also be found necessary for the relief of the pain to employ the nitrites, diuretin, bromides, counter-irritants, and diathermy as in primary angina. It is important, for its psychological effect on the patient, to emphasise the secondary nature of the heart affection.

*Neurasthenic Cases.*—It is important to stress the symptoms which can be explained on other grounds than those of cardiac disease, and to avoid emphasising such symptoms as are cardiac in origin. In this way the attention of the patient can be deflected from the heart. If the symptoms can be attributed to the stomach the treatment then becomes one of diet, carminative mixtures, and a judicious use of sedatives. Many of the drugs recommended for the treatment of primary angina can be usefully given in cases of angina of this type.

## AN ATTEMPT TO PROVIDE A STANDARD DEATH-RATE FOR BRITISH MERCHANT SEAMEN.

By Fleet Surgeon W. E. Home.

### Part I.

The President of the Board of Trade has told us (Hansard, April 9th, 1925) that a death-rate for merchant seamen cannot be prepared, and what he said was lamentably true. Still, an approximation may be made, and it is worth attempting, for it will show how much greater are the sailors' risks than are those of men in other callings, risks both of accident and disease, and if this sinks into the public conscience a planned attempt to reduce them may be set on foot. A wise critic, writing on this subject, suggested that a death-rate in regard to one calling was apt to mislead, being so little comparable with those of the general population in consequence of the different age distributions. It seemed, therefore, that an attempt must be made to get out a standard death-rate for merchant seamen before people would pay heedful attention.

And, indeed, it may seem absurd to set out to find even an approximate standard death-rate for merchant seamen when we have no information that is accurate or generally accepted as to their number, or as to the total of the deaths attributable to the industry in any year, while even the names of the diseases from which they died are less certainly known than are those of other persons; for sailors' deaths are often named only by captains of ships, admittedly shrewd men, or by other less trustworthy observers, but who are not doctors. Still, the fact that there are these uncertainties only makes it more expedient for the question to be examined as thoroughly as possible, so that the health level of the merchant service with all its risks may be put before the profession as completely and as exactly as possible.

The last official statement professing to give a complete account of the death-rates of "occupied" merchant seamen is in Part II. of the Supplement to the Sixty-fifth Report of the Registrar-General (Command Paper 2619 of 1908), a pendant to his report on the 1901 census. It was published in 1908, and concerned itself with English occupational mortality as evidenced among the registered deaths of workers whose brethren had in that census stated themselves as belonging to one or other of its hundred occupational groups. The deaths amongst such people that occurred in England and Wales during 1900, 1901, and 1902 were assembled according to the occupational groups, and according to ages in those groups, and according to the causes of the deaths, and were then divided by three times the census population at each age and group that the appropriate death-rate should be found. Two sets of tables were prepared, one for the "occupied" in each calling, the other for the "occupied and retired." In this paper we are concerned only with the "occupied." To make comparison of the health conditions in the groups easier, there were also calculated "Comparative Mortality Figures" for the men in each calling between the ages 25 and 65, those ages being selected as giving a fair impression of the risks incurred by men who had settled down to carry on their occupations. In the earlier years the numbers in each group kept increasing as new recruits came forward, but from 25 onward the totals gradually decrease. The "C.M.F." were chosen as they were because it was observed that in 1900–02, 281,009 deaths had been registered among "All males, occupied and retired" of ages 25–65, of whom 6,722,009 had been enumerated in 1901; that is, 1000 deaths had occurred among every 71,005 males, and deaths were stated not as in death-rates per 1000, but per 71,005 men (the comparative mortality figure being the death-rate multiplied by 71·005). The basic or unit figure, 1000, the comparative mortality figure for "All males, occupied and retired," is equivalent to a death-rate of 14·08.

Among the greater occupations employing over 100,000 men daily, the highest C.M.F., 1987, was found among the "general labourers." That for merchant seamen was 1547, equivalent to a death-rate of 21·78, 50 per cent. above the average (14·08), as the C.M.F. directly shows.

In his summary dealing with the health conditions of different callings, Dr. Tatham, who prepared the report, observed (merely on the figures before him it should be said: later they will be shown to be incomplete) that "the seamen's loss of life from accident was nearly four and a half times the average among all occupied and retired males generally (260 against 59)" and further noted that, though decreasing, "their mortality from phthisis is still excessive (249 against 187)."

In Table V. of the report (p. clxxxiii.) there are stated, for a score of selected causes of death, in the middle of each page as a mean, the comparative mortality figures for "All Occupied Males," and above that some 30 groups who had the heaviest, and below some 30 who had the lightest mortality. In these lists merchant seamen come to notice as suffering unusually heavily from diseases of the nervous, circulatory, digestive and urinary systems, also from cancer, while having besides the heaviest mortality from accident.

A similar report, dealing with 1910–11–12, would doubtless have appeared by 1918 but for the war. Indeed, part of it, relating to "occupied and retired," was issued in 1923, but does not concern us here. The report appropriate to the census of 1921 is now in preparation, but as it has not yet appeared, the 1908 report is the latest official summary by the Registrar-General of the mortality among "occupied" merchant seamen.

Table I. below shows certain figures from the 1908 report that have interest as they concern seamen and some of the larger groups. The number of men in each group are stated, and then, for ages 25–65, the chief cause of mortality in the group, next, the comparative mortality figures for deaths from all causes, and from phthisis and accidents which are the chief risks of seamen; the corresponding death-rates are then stated for convenience. At the right-hand end of the table are the similar death-rates for the youngsters who join the trades, ages 15–20 and 20–25. The last line at the foot gives the figures for the Royal Navy in 1901, very much less than those of the Merchant Marine; but the Navy is a much younger service, having, in 1901, 61 per cent. under 25 years of age, while the other service had only 52.

In our examination of this table we will notice that between ages 25 and 65 the highest figure for total deaths and for deaths from phthisis were those of "general labourers," but that seamen in the Royal Navy had a very high death-rate from accident, though it was only half that of their professional brethren in the Merchant Marine, who had besides nearly three times the death-rate from phthisis the coal-miners had, and twice their death-rate from accidents. Between ages 15 and 20 merchant seamen had by far the highest death-rate from accidents; while coal-miners had three times the average, merchant seamen had a death-rate three times greater still—nine times the average. From ages 20 to 25 conditions are very similar, merchant seamen having again the highest death-rate of all, one very high for phthisis and the highest for death by accidents. It will also be observed that the young (ages 15–25) seamen in the Royal Navy had a risk of death from accidents higher than that of any other employed males, excepting only those of the merchant service. We should observe, too, how the risk of death from phthisis increases after 20 years of age. The mortality of agricultural labourers and coal-miners from phthisis is very similar at all ages, but that of merchant seamen is always about three times as great—six times above that of the Royal Navy, though only twice as high from accident. From all of which we learn from the Registrar-General that boys who go to sea take on them a double risk of phthisis, but nine times the ordinary risk of death by accident. As Horace, though he did not know all this any more than they do, truly remarked, *Illi robur.*

This table, and the conclusions we have been able to draw from it, emerge from a Government publication of 1908 *discussing conditions of 1900–02, not to-day's;* but they suggest that at that time, 20 years ago, merchant seamen had a mortality from all causes and from phthisis 50 per cent., and from accidents 400 per cent. greater than that of the ordinary citizen. Yet even here we have not a full statement of the risks of merchant seamen at that time.

It has long been complained by those who concern themselves with the health records of merchant seamen that there are no complete statistics of the deaths that occur amongst them, a complaint voiced *most clearly* and with fullest knowledge by Dr. J. Howard-Jones, M.O.H. of Newport (Mon.), whose paper in the *Journal of the Royal Sanitary Institute* (1915, p. 124) will well repay re-perusal. As he points out, we have two sources of information about the deaths of seamen, one the occupational mortality supplement to the Registrar-General's report on each census, which we have just been considering, the other the return of the deaths of seamen, issued annually by the Board of Trade. Unfortunately, as Dr. Howard-Jones remarked, they are not complementary to one another, and cannot be combined to give us the whole truth. Deaths of seamen occurring abroad are not registered with the Registrar-General, and do not come into his calculations at all. Thus he reports (1900–02) an average annual number, 354, of deaths among merchant seamen from accidents, but the Board of Trade put the deaths from accidents in 1901–02—not, so far as appears, an exceptionally heavy year—at 973 (unpublished return I was kindly allowed to see at the Board of Trade and copy). This figure suggests that seamen have a death-rate from accident far higher than the Registrar-General propounds, a death-rate of 7 or 8, instead of 3·75. On the other hand, the Registrar-General's average for deaths from phthisis being 301, the Board of Trade only mentions 45. Why is that? The explanation lies in the purpose of the Board's return, and in the nature of that chronic and insidious disease. The Board of Trade only concerns itself with the deaths of seamen while on ships' articles or in the hospitals to which they have been discharged sick from their ships; it has nothing to do with them before or after. So a man found at Port Said to have phthisis and there discharged to hospital will, if he die on the spot, be noted in the return; but if he recover sufficiently to take passage home after his discharge, and subsequently dies at home without again going to sea, his death will not be shown in the Board's return; it will be registered with the Registrar-General, when, if the local registrar elicits from whomever does register the death that the deceased was a sailor, his death will be classified with those of seamen, and if otherwise, otherwise. Then there are also the cases, discussed by Dr. Howard-Jones, of the men who, having begun while employed as seamen to develop phthisis and so to lose strength, realise they are not fit for work at sea and consequently take up some other lighter trade and die in that; these men are no longer mentioned as seamen, though it was in ships their phthisis was contracted. It will be convenient here to put side by side (Table II.) the Registrar-General's account of the deaths *of merchant* seamen, taking the average of three years, and the Board of Trade's statement for 1901–02.

When these are examined it becomes clear there is no relation between them. The populations stated for each are so very different, and [the figures shown in Table III.] evidence the very various distributions, per 1000, of the ages among the 97,065 seamen who, in the census of England and Wales, stated seafaring as their occupation (Registrar-General), and among the 117,558 * seamen who gave their ages (15–75) when the census was taken on board British ships throughout the world (Board of Trade), both on March 31st, 1901. The differing distributions suggest that of the younger men more are abroad, as there are more in the census of seamen, of the older more at home, and so more older men amongst the seamen in the census of England and Wales. The figure, 140,860, is the probable number of British seamen in the "first crews" of British ships, annually mentioned by the Board of Trade as an indication of the number of seamen there are. It is quite valueless for calculating a death-rate. On the whole, the Board of Trade's return probably gives an exact figure of the deaths of seamen in their ships, and a tolerable approximation to the causes, but it gives us no population figure by which to calculate a death-rate, as Sir P. Cunliffe-

---

* This figure on Table II., given as 120,412, includes "age not stated."

Lister allowed, and it neglects all deaths, sequelæ, of illnesses contracted in ships and not immediately fatal—all deaths, in fact, which occurred after discharge. It is, therefore, an under-statement; on the other hand, the Registrar-General's account, while including many of these deaths, does not concern itself with those occurring outside England and Wales, and its total population figure gives too small an idea of the number of seamen that there are.

* Direct and contributory.

That the Registrar-General gives six times as many deaths from phthisis (304) as are found in the Board of Trade's return (45), rather supports Dr. Howard-Jones' opinion that for every man who dies of phthisis in his ship, and is noted in the Board of Trade's return, there are nine others attacked. This under-statement of phthisis deaths, Dr. Howard-Jones tells us, led a former President of the Board of Trade to try to prove that phthisis was less fatal at sea than on shore, which we know is not the case. Similarly, it will be noticed, the Registrar-General gives for pneumonia 145 deaths annually, but the Board of Trade, for 1901–02, only 50. It seems likely that some of these others occurred while men were waiting for ships, and were due to bad lodging, insufficient food or clothing, in various proportions. The figures for cancer, 132 and 6, are also strikingly different. A word must be said about deaths from alcohol. The Registrar-General gives 27, probably all acute; the Board of Trade shows 19 due to acute alcoholism, but separates 10 from the "suicides" and 91 from the deaths from accident as deaths "to which drink was a contributory cause." In the re-arrangement of the lists necessary so that they might be compared, these have all been included under alcohol, to which the deaths are more properly attributable.

It must now be clear to all that in 1900–02 there was no complete account anywhere of the causes of the deaths of seamen, but that what figures there were showed that 20 years ago the mortality in this employment was very high indeed, judged by the experience of other trades. In the second part of this paper endeavour will be made to show how the figures available for the deaths of seamen in 1921 appear to compare with those for the rest of the population. Fortunately, great and beneficial changes have occurred at sea in the interval. Food and cooking are better, and accommodation also. Mr. Havelock Wilson, in his wonderfully interesting book, "My Stormy Voyage through Life" (p. 200), says it is now quite common for owners when building a new ship to consult the National Sailors' and Firemen's Union as to possible improvements. That sailing ships are dying out has greatly diminished the number of deaths from accidents. Another great benefit, the provision by the Ministry of Health of treatment centres for venereal diseases, their extension to foreign ports, and the International Treatment Card (V. 44), promoted by the British Social Hygiene Council to secure continuous, consistent treatment, will in a few years materially lessen the deaths of seamen.

Table III.—*Proportion of Age-Groups per 1000 Men in 1901.*

| Ages. | Regist.-Gen. Census of England and Wales. All males. | Regist.-Gen. Census of England and Wales. Merchant seamen. | B. of T. Census of Seamen. Merchant seamen. | Royal Navy. |
|---|---|---|---|---|
| 15–20 | 156 | 88 | 98 | 609 |
| 20–25 | 143 | 156 | 200 | |
| 25–35 | 122 | 143 | 167 | 297 |
| | 121 | 143 | 167 | |
| 35–45 | 94 | 105 | 104 | 78 |

| 45–55 | 68 | 75 | 59 | over 45 16 |
| | 68 | 75 | 59 | |
| 55–65 | 44 | 41 | 19 | |
| | 44 | 41 | 18 | |
| 65–75 | 23 | 14 | 2½ | |
| | 23 | 14 | 2½ | |
| | 1000 | 1000 | 1000 | 1000 |

But 1921 must be left to another occasion, and in the meantime we may reflect on the curious arrangement which takes the men the Ministry of Health has cared for all their childhood and most of their youth, transfers them to the less expert medical care of the Board of Trade for their working life, and then returns them, many of them "broken in the wars," again to the Ministry of Health, which has had no watch over them meanwhile. Surely it would be better that the Ministry of Health should have the responsibility for them throughout. It would then, in five years anyway, be able to tell us, though that is beyond the Board of Trade just now, what is the absolute waste of life due to seafaring—not really a very difficult matter for medical experts. Then the industry would know what insurance should be paid for each man, and the invalids would not be unloaded on to the public, as no doubt happens now, however much is borne by charity. Then the Ministry of Health, continuously responsible for the health of merchant seamen and for their insurance funds, would be encouraged, for financial reasons, to enforce the best preventive measures, for, unlike the Board of Trade, it would remain responsible, not only for the men sick and injured while they were in service, but also for the invalids after discharge, whose number it would have every interest to reduce, and every inducement to see were kept revenue-producing and self-supporting, as long as possible.

The late Dr. W. A. Holmes.—After 40 years of general practice in Barrow Dr. William Albert Holmes died on March 29th at the age of 68. He graduated M.B., C.M. at the University of Edinburgh in 1884, became M.D. with honours two years later, and took the D.P.H. at Cambridge in 1890. As a young man he was a keen cricketer. For many years he was surgeon to the borough police, and his work in this appointment was much appreciated in the district. Dr. Holmes's wife died about a year ago; he leaves two sons and a daughter.

# MEDICINE AND THE LAW.

### *Death from Unnatural Cause: Common Law Duty to Notify.*

DURING the debate on Mr. Tinne's Births and Deaths Notification Bill, Sir Richard Luce moved an amendment that where the cause of death was unknown to the medical practitioner, or where death appeared due to violence, neglect, poison or other unnatural cause, or seemed to be the result of an anæsthetic, he should not grant a certificate, but should forthwith report the circumstances to the coroner. This Sir Kingsley Wood resisted on the ground that the amendment would impose as a statutory duty what was already the duty of the medical practitioner at common law, apart from statute. This objection was legally correct, but so little is this common law duty known that there would have been no harm in embodying it in statutory form. At common law there is a duty upon any person about the deceased to give notice in such a case if Parliament has not already thrown upon any particular person the burden of informing the coroner of the death. It is not a duty of the doctor as doctor, but of any person who is in a position to give the information. This common law duty is complied with either by informing the coroner's officer or by telling the nearest policeman. Its origin is very ancient. It goes back to the twelfth and thirteenth centuries, when the finder of a person feloniously slain was expected to raise the hue and when townships might be amerced for failing to send for the coroner. Exactly what is the purport of the word "hue" it is hard to say; we know it best in the form "hue and cry" (*hutesium et clamor*). Possibly, said the late Prof. Maitland, the proper cry was "Out! Out!" and therefore the word is *uthesium* or *hutesium*. At any rate, out the neighbours would come with their bows and arrows and their knives and there would be shouting and horn-blowing, and the hue would be "horned" from vill to vill. But we no longer live in the age of bows and arrows; we no longer raise the hue and follow the cry. Sir Richard Luce's amendment would have laid down some definite guide for the medical practitioner in doubtful cases, and it is perhaps a pity that he was induced to withdraw it on the ground that it might have infringed the obscure and almost obsolete procedure under the common law.

### *Dangerous Drugs Act Prosecution: Failure to Enter Purchase in Register.*

Dr. Samuel Grahame Connor, of Dryden Chambers, Oxford-street, was summoned at Marlborough-street police-court at the end of last month for failing on three occasions to enter, in a register kept for the sole purpose, a certain quantity (50 gr.) of morphine purchased by him. A fourth summons charged him with failing, in a prescription of morphine, to specify the address of the person for whom the prescription was given. Dr. Connor pleaded guilty to the four charges, and was sentenced by Mr. Cancellor to two months' imprisonment in the second division on each of the first three, and to a fine of £50 on each summons, making six months' imprisonment in all and £200 fine. Notice of appeal was given.

Dr. Connor was stated by the police to be a drug specialist and to have as patients several addicts known to the police. One of these, a Miss Young, had been convicted of forging a prescription in Glasgow, and Dr. Connor was found to be sending her morphine from London. When told that she was being treated by another doctor, Dr. Connor said he would discontinue treating her himself. A year later she was again interviewed by the police, and in the sequel an inspector called to see Dr. Connor's register. Dr. Connor kept no register, but produced a day-book showing dates on which prescriptions had been given. Between Jan. 25th and Dec. 27th of last year, it was stated, he had prescribed 575 gr. of morphine on 13 occasions and had only seen the patient six times. A firm of chemists produced their register showing in all 850 gr. ordered; only one prescription was for Miss Young; there were many orders signed by Dr. Connor and headed "for surgery use only." These orders, the prosecution contended, were not "prescribing" but "supplying" within the meaning of the Dangerous Drugs Acts. On behalf of Dr. Connor it was urged that his day-book was open to inspection and that no attempt was made to mislead anyone or conceal anything. The magistrate, however, refused to treat the case as a merely nominal breach of regulations, and, apparently influenced by the suggestion that the accused had been amply warned by the police and that his drug practice was on a substantial scale, inflicted what certainly seems a remarkably severe penalty.

---

# IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *Census of the Irish Free State.*

ARRANGEMENTS are now complete for taking a census of the Irish Free State, and "Census night" is fixed for April 18th. Forms have been distributed by the Civic Guard, and their collection will begin on Monday. The form, which is in English and Irish, contains 18 columns, in which information is required concerning occupation, nationality, birthplace, race, language, religious beliefs, conditions of marriage, relation to head of family, issue born in marriage, and houses and buildings inhabited or uninhabited or in course of erection.

### *Women's National Health Association.*

The annual meeting of the Women's National Health Association was held last week under the presidency of the Marchioness of Aberdeen and Temair. Dr. Alice Barry, in a report on the working of the babies' clubs, mentioned that the membership of the clubs was 8451; attendance of mothers at clubs, 27,166; infants, 17,098; and children, 20,082. There had been 10,040 medical consultations and 287 cases had been sent to fresh air and convalescent homes. Drugs and food had been distributed by the clubs at a reduced rate, or free to necessitous cases. Prof. J. W. Bigger moved a resolution urging public authorities to provide for the protection of milk, to ensure a free supply for children of from 1 to 5 years of age, and to make the public understand the value of milk as a food and the importance of having it hygienically treated. Dublin milk was very bad, but the increased demand for bottled milk showed that people were taking an interest in having better milk. Bottled milk, however, might be as dirty as any other. The public health authorities should, he suggested, protect the terms "Certified," or "Grade A," in relation to milk. There was at present no milk reaching Dublin under "Grade A" conditions. Other articles of food as well as milk required care in production and sale.

### *Queen's University of Belfast.*

The late Right Hon. J. C. White, formerly Lord Mayor of Belfast, left a bequest of £60,000 to Queen's University to endow a chair of biochemistry and lectureships in that subject and in bacteriology. The new biochemical laboratory was inaugurated on March 26th. The Vice-Chancellor of the University, who presided, pointed out the great and growing importance of biochemistry; it seemed to be the department in which most progress was to be hoped for in the immediate future. The Lord Mayor of Belfast, Sir W. P. Turner, in proposing a vote of thanks to Mrs. White for unveiling the memorial tablet, dwelt on the public services of her late husband, and on the prosperity and progress of the Belfast Medical School. Prof. J. A. Lindsay, in seconding the motion, pointed out that universities were largely dependent on private benevolence, for experience had shown that they could not expect to derive more than a third of their income from students' fees. The contributions of the State and of municipalities to university education had in the past been somewhat meagre, but recently there had been some advance. America gave a splendid example of private beneficence in support of universities, and the proportion of university students to the population in that country—1 to 300—was the highest in the world, Scotland being a good second with 1 to 400, and Germany third with 1 to 600. He hoped that the White bequest would be a stimulus to further benevolence in Northern Ireland.

The chair of biochemistry is held by Dr. J. A. Milroy.

# Public Health Services.

## THE INFLUENZA EPIDEMIC IN GLASGOW.

Although reports in the daily press have exaggerated the position, there has undoubtedly been an epidemic of influenza in Glasgow during the last few weeks. Dr. W. G. Clark, assistant medical officer of health for the city, has kindly supplied us with the actual figures of deaths from certain causes during the five weeks ended April 10th. These are as follow:—

| — | Week ending— | | | | |
|---|---|---|---|---|---|
| | March. | | | April. | |
| | 13th. | 20th. | 27th. | 3rd. | 10th. |
| Influenza .. .. .. | 2 | 8 | 25 | 60 | 83 |
| Pneumonia . .. .. | 31 | 39 | 87 | 119 | 98 |
| Bronchitis .. .. .. | 14 | 20 | 38 | 54 | 36 |
| Other respiratory diseases | 7 | 4 | 5 | 7 | 4 |
| Encephalitis lethargica .. | — | — | 1 | 4 | 1 |
| Total deaths from all causes | 295 | 346 | 452 | 598 | 484 |
| Death-rate per 1000 .. | 15·4 | 17·4 | 22·5 | 29·3 | 24·1 |

The normal number of deaths from pneumonia in Glasgow at this season is round about 30 per week, while those from influenza are usually under 10. In January of 1922 and March of 1924 there was a definite prevalence of both these diseases, that of 1922 being heavier than the present. Contrary to current popular statement there has been no significant increase in the number of cases notified as encephalitis lethargica during this period.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 3rd, 1926.

*Notifications.*—The following cases of infectious diseases were notified during the week:—Small-pox, 130 (last week 178); scarlet fever, 1564; diphtheria, 970; enteric fever, 42; pneumonia, 1376; puerperal fever, 38; cerebro-spinal fever, 5; acute poliomyelitis, 4; encephalitis lethargica, 38; continued fever, 1; dysentery, 7; ophthalmia neonatorum, 93. There were no cases of cholera or plague notified during the week. There was no further case of typhus fever notified during the week, although the return omits to state so.

*Deaths.*—In the aggregate of great towns, including London, there were 8 (1) deaths from enteric fever, 107 (44) from measles, 8 (2) from scarlet fever, 66 (8) from whooping-cough, 50 (16) from diphtheria, 46 (10) from diarrhœa and enteritis under 2 years of age, and 223 (48) from influenza. The figures in parentheses are those for London itself. The notified deaths from influenza are 87 in excess of the previous week. The measles deaths have now exceeded 100 for seven weeks in succession.

The late Dr. J. A. Guthrie.—Dr. James Ashton Guthrie, who died at his home at Halifax on April 3rd in his 85th year, was the son of Mr. Daniel Guthrie, of Brierley Hill, Staffordshire, and was educated at Queen's College, Birmingham. As a young man he went to Halifax as an assistant, and seven or eight years later moved to Edinburgh, where he remained for five years until in 1885 he took his degree as M.B., C.M. Returning to Halifax he remained in general practice until 1911. He was keenly interested in scientific developments and was an active member of the Halifax Scientific Society.

"Audi alteram partem."

## THE PROBLEM OF MALIGNANT DISEASE: A VIEW.

*To the Editor of* The Lancet.

Sir,—In the Registrar-General's Statistical Review of England and Wales for the year 1924 it is stated that the mortality from cancer has been steadily rising since 1884, and during 1924 there were more deaths from this cause than in any previous year for which official records had been kept.

In the face of such an official statement, is it not time we began to question the wisdom of our present methods and seek something better if it can be found? Surgery has failed to meet the situation, and we have the testimony of one of the most eminent members of this branch of the profession that no further elaboration of surgical technique can make any difference; so that it may fairly be said that we have arrived at a "dead end." The mortality steadily increases—this in spite of the fact that surgical methods and technique have been steadily improving year by year. Also it is to be remembered that the surgeon has the best possible chance to make good. All cases come to him in the first instance. He keeps the early and operable ones to himself, passing the inoperable and hopelessly incurable on to others. His statistics are naturally based on the former and yet the results are scarcely satisfactory, as most surgeons are quite ready to admit. Such, very briefly, is the present situation, and however much we may wish to change it the alteration is not going to be an easy one.

An important reason for this is the present tendency for patients to be taken directly to the specialist in a particular method of treatment, and on the principle that "there's nothing like leather," his own methods are used. For this reason, among others, I deplore the elimination of the pure consultant from our medical service. From him at least we could count on getting some sort of independent opinion—more than can be said of our present system, which is not only antagonistic to the best interests of the patient, but is a formidable barrier to progress in the healing art.

It is a cardinal principle of medical service that when we are called upon to deal with some disability we should exhaust the possibilities of such curative agents as are at our disposal before resorting to surgical interference. The most important exception to this rule is malignant disease, and however correct this may have been at one time it is very doubtful if it can be considered so now.

Of the multitude of things that from time to time have been suggested as a possible cure for malignant disease, the gamma ray as derived from the X ray tube or from radium is the only one that has shown itself to have any real value. (It is true that lead is showing some promise, but while hoping for the best we must be patient for the present.) The fact that the ray has a more than ordinarily prejudicial influence on the development of the malignant cell has been known to us for nearly 25 years, and the question naturally arises: What have we done to establish the real and full value of radiation in malignant disease?

Personally I am of the opinion we have done very little, but I hope I may not be misunderstood. I know that an enormous amount of work has been and is carried on, and it is far from my wish to disparage it in any way, but almost all of it is concerned with advanced cases, many hopelessly incurable, and also those that have been through the hands of the surgeon, which seriously impairs any chance of success from radiological methods. Experience gained under such conditions has its value, especially if it serves to give relief to the patient and prolong life under comfortable conditions. It teaches us no more, however, than we have known for a long time past, but as for dealing with the main problem we are not getting any "forrarder."

Notwithstanding the magnificent work that has been done at Erlangen for years past it never seems to occur to anyone here to give radiation a chance to show what it can do, in competent hands, for cases of malignant disease in early and curable stages, and before the surgeon has so mutilated the tissues as to make radiological methods ineffective. Under present conditions once a case is turned over to the radiologist it means, with very few exceptions, that it is only a question of time, and seldom a long one. So that while we have at our hand an agent which by general admission possesses curative powers over malignant disease, our general practice is to confine its use to the less curable cases.

Let us consider for a moment what has been going on in the Erlangen clinic for some years past. In my original communication to the Royal Society of Medicine in December, 1920 (THE LANCET, 1921, i., 24), I related the results obtained in carcinoma of the uterus—such cases as would be deemed favourable for operation here and dealt with accordingly. These results were so superior to those obtained by surgical methods that for some time surgery had been abandoned for cases of malignant disease of the female pelvis, and now five years later, this is still the rule of the clinic. The attitude has been to discredit these claims; yet Prof. Wintz's clinic has been freely open to anyone who cares to come and make an honest investigation, and it is quite certain that if there was anything about it that was not quite straight it would have been found out long ago, and incidentally the practice of the clinic would have been altered. Furthermore, Prof. Wintz attended the First International Radiological Congress held recently in London, in the course of which he gave his results of the X ray treatment of cancer of the breast. Here, again, the results were uniformly better than obtained by surgery, and, as he rightly emphasises, only the results obtained by the best surgeons are admissible for comparison.

It might be thought that some very serious notice would have been taken of a communication of such overwhelming importance. One almost blushes to relate that it has been passed over with scarcely a nod of recognition, those who now have the first say in the treatment of cancer in this country not welcoming the new departure. They base their attitude on the contention that early operation is the best and only method of dealing with malignant disease, and what with constantly preaching this doctrine, teaching it to students, and the publication of articles and pamphlets for public consumption, the profession and a large part of the educated public have got the idea that there is no treatment for malignant disease and that the only hope lies in the efforts of the surgeon. Enthusiasts are working hard at cancer research all over the country, but for all the time, work, and money spent they have not brought us appreciably nearer the desired end.

If I were asked the main reason for this failure I would say it is because all this work is dominated by the surgical view, which is definitely antagonistic to any change in present practice. How else are we to account for the fact that as yet no proper effort has been made in this country to test the results obtained at Erlangen? There are plenty of sets of apparatus such as are used there, and we have men in charge of them quite able to use them to the best advantage—if they get the chance. But the surgeon retains the favourable cases, and on these he bases his statistics. All the advanced and inoperable cases, as well as the failures of his own work, he passes on to the radiologist, and it is on the results attained on these—quite beyond surgery to cope with—that he bases his opinion of the value of radiation in malignant disease. For those who are prepared to go into this question with an open mind there is ample evidence to show that when working under equally favourable conditions radiology can show at least as good results as surgery without any of the risks and mutilations involved in the latter. While it may be a fine thing to relieve a patient of a malignant lesion by operation, it is a much finer thing to get the same result leaving the individual intact. That this can be done is shown by the results attained at Erlangen, and I firmly believe in the possibility of repeating them here because of the high degree of success I have had in the relatively few early cases of malignant disease that have been referred to me before there had been any surgical interference. I wish to emphasise the fact that success after radiation depends on free and active blood and lymph circulations. This essential condition cannot be met in an area that has been the site of surgical interference, and this is one more, and a very important, reason why, if we are to make any definite progress in our methods of dealing with this problem, the surgeon's attitude must alter. Surgery can secure but a very moderate degree of success; alternative methods are tested only under the most unfavourable conditions.

I think it is more than time the Erlangen technique were given a fair and honest trial, and if carried out faithfully I predict with the utmost confidence that the lot of the unfortunate victim of malignant disease will be altered for the better—mentally, physically, and materially. I appeal to the profession as a whole, and particularly to general practitioners, to look into this question most carefully; to accept no evidence from either surgeons or radiologists as gospel truth, but only at its real value, allowing a reasonable discount for personal interest, and see if it does not seem worth while giving their patients an alternative to the knife—the most crude method of dealing with any disease our unfortunate bodies are called upon to bear. I am, Sir, yours faithfully,

REGINALD MORTON.

Park-crescent, Portland-place, W., April 7th, 1926.

# A COMPENSATION PROBLEM.

*To the Editor of* THE LANCET.

SIR,—Your correspondent "Practitioner" (THE LANCET, April 3rd, p. 730) asks for views on the relation of injury to tumours of the testicle. A history of preceding injury to the testicle is obtained in 10 to 20 per cent. of the cases of testicular tumour—some writers give a higher figure—and the majority of observers incline to regard the injury as a definite cause of the neoplastic process. But, as I pointed out in a recent Hunterian lecture, it is difficult to reconcile this view with the fact that, although almost every active male receives at some time in his life a severe blow on the testicle, tumours of the testicle are rare. On an average three cases are treated in each year at the London Hospital. From an extremely interesting case reported at some length in my lecture it appears most probable that the part played by injury is not to initiate the neoplastic process, but rather to stimulate to more rapid growth a pre-existing but hitherto unobserved tumour. Whichever of these views be the correct one there is a case for compensation if it can be proved that the testicular swelling only became apparent after an injury to the testicle. But there is no reason at all to suppose that an injury limited to the back, such as occurred in the case brought forward by "Practitioner," could have any possible influence on the behaviour of a scrotal testicle.—I am, Sir, yours faithfully,

H. W. B. CAIRNS.

London Hospital, E., April 6th, 1926.

*** Mr. Cairns's lecture will shortly be published in THE LANCET. We have received other replies to "Practitioner's" questions from surgeons who desire to remain anonymous. One writes: "Some important points are wanting in the clinical history supplied by 'Practitioner.' Was there any direct injury to the testicle, and did the patient report pain or tenderness immediately after the accident? Was there any subsequent swelling of the testicle or bruising of the scrotum? Was the testicle fully or imperfectly descended? Was the growth of the mixed form that is recognised as congenital?

"Assuming that there was no local injury to the testicle, the growth could not, by any stretch of imagination, be ascribed to the injury. A single direct injury on normal testicles has not, so far as I know, ever been proved to cause a new growth. It has been claimed, although I very much doubt it, that repeated injuries to an imperfectly descended testicle are the cause of new growth. If the testicle was imperfectly descended there is no need to attribute the growth to a single injury, for the frequency with which growth develops in such a testicle, apart from injury, is recognised. If the histology is that of a mixed growth, the congenital origin, apart from injury, is clear. In any case there is nothing to connect the appendicitis with the injury or with the orchidectomy."

Another surgeon writes: "In regard to the testicle, it is well known that in the majority of testicular tumours there is a history of injury some time before the appearance of the tumour, and the injury is accordingly accepted as having some ætiological significance. In this case, however, we can safely assume that the tumour was a very slowly growing one because 18 months were allowed to elapse between its recognition and its removal; and as the injury occurred only four weeks before the first recognition of the swelling in the testicle, one is safe in maintaining that it must have been present before the accident. Arguing on these lines I feel confident that a claim for compensation cannot be maintained. In respect of the attack of acute appendicitis I should give a strong expression of opinion against the accident having had anything to do with it at all. Trauma as an ætiological factor in appendicitis is a very debatable point and the balance of opinion is against it. Anyway, in this case it seems out of the question to blame an accident 19 months previously for a subsequent attack of appendicitis."—Ed. L.

## UROTROPINE, CITRATE OF SODA, AND BROMIDE OF AMMONIA IN THE TREATMENT OF EPILEPSY.

*To the Editor of* The Lancet.

Sir,—Recently I have investigated the treatment of epilepsy in the light of my belief that an important factor in the causation of this disease is the colon bacillus; and the one outstanding result of my investigations is the discovery that the power possessed by ammonium bromide of preventing epileptic fits is decidedly raised by administering with this remedy urotropine and citrate of soda. In almost every case of fits under my care I now give two separate prescriptions, as follows:—

(1)

℞

Ammonium bromide .. ʒiv
Urotropine .. .. .. ʒii
Chloroform water to .. ℥vi
Sig.: Take one tablespoonful in water night and morning.

(2)

℞

Sodium citrate .. .. ℥vi
Sig.: Take one teaspoonful in half a tumblerful of water night and morning.

Under the action of the medicines shown in these two prescriptions the fits in all my cases have so far disappeared. In one remarkable case of hystero-epilepsy, where attacks were occurring at the rate of three to eight a day, and where 20 gr. of bromide, thrice daily, failed to control them, the use of these prescriptions in a short time caused them to cease. The following is a record of a case which has been under observation for a considerable time.

A. B. C., a male aged 44 years, has been suffering from fits for 20 years. From 1907 to 1917 he took, without much benefit, about 20 gr. of bromide twice daily. In February, 1917, he came under my care, and although I gave him large doses of the mixed bromides night and morning, he continued to have fits at varying intervals to September, 1924. The following is an accurate account of his seizures: 1917, six; 1918, nine; 1919, ten; 1920, four; 1921, seven; 1922, six; 1923, six; 1924, four. On Sept. 16th, 1924, I prescribed 20 gr. of bromide of ammonia to be taken night and morning, and one teaspoonful of citrate of soda to be taken with each dose of bromide. Subsequently I added to each dose of the bromide mixture 10 gr. of urotropine. The result is that the patient's fits have ceased and that up to the date of writing there has been no recurrence.

No unpleasant by-effects have appeared in any of the cases treated with urotropine and citrate. I have also tried benzoate of ammonia, but as this seemed in some instances to depress the patient's spirits and to derange his digestion I have nearly ceased to prescribe it. Further investigation will show to what extent the daily dose of bromide could, in course of time, be reduced.—I am, Sir, yours faithfully,

E. J. McC. Morris, F.R.C.S. Edin.

Poynders-road, S.W., April 10th, 1926.

## FAMINE IN THE TROPICS.

*To the Editor of* The Lancet.

Sir,—In my letter on the above subject which appeared in your issue of March 13th, on referring to the "1 lb. ration" instituted by the Government of India against the strenuous advice of Cornish, I stated "from Jan. 31st, 1876, to May 22nd, 1877, this diet was in force." In both instances the year quoted should have been 1877. As the context shows famine was not officially recognised till October, 1876, the discrepancy is apparent; but seeing that the results of error in nutrition both in individuals and populations must be estimated not only as to its nature but in the light of duration of its incidence, I venture to ask your permission to correct the slip of diction for which I am responsible, lest the casual reader be misled. Had the "1 lb. ration" been in force for the longer period, a diminution not of 3,000,000 of the population of the affected districts, but a great multiple of that number would have been inevitable.

I am, Sir, yours faithfully,

W. G. King,
Colonel, I.M.S. (retd.)

Hendon, N.W., April 5th, 1926.

## POSTURE IN EMPYEMA CASES.

*To the Editor of* The Lancet.

Sir,—In Mr. Twistington Higgins's most interesting article on empyema in children which appeared in The Lancet of March 20th, there is one piece of advice with which I would join issue. It reads as follows:—

> "Once the tube is out the child should be encouraged to lie on the good side and deep-breathing exercises should be continued."

Presumably this indicates that it is the opposite side—i.e., the side where the resection of the rib was made—which will be given thereby a chance of functioning better than the sound side on which the patient is advised to lie. In an article of mine which appeared in The Lancet of April 26th, 1919, p. 697, on Gunshot Wounds and Other Affections of the Chest I wrote:—

> "Great assistance in making a collapsed lung function properly is rendered by bending the body away from the injured side, as the patient lies on his back. This position causes a partial collapse of the sound lung by mechanical pressure of the ribs. Also, when possible, the patient should lie on the injured side when preparing for sleep."

I have often been questioned about this advice, doubt being cast on the idea that it is the lung on the side on which the patient is lying that is getting more air than the opposite lung. From careful observation I believe that this is really so. The side on which the patient lies sinks into the bed in a convex position and apparently the lung functions freely, the opposite or upper side is mechanically compressed by the position assumed, and expansion is restricted. I therefore always advise patients with an empyema to lie on the back, as described, or on the side where the rib has been resected, both from a drainage point of view and for expansion of the lung.

I am glad that Mr. Higgins advocates having breathing exercises applied very soon after operation. Five days after operation is the earliest time in which I have been asked to give exercises, and in the war the average time was about 12 days. Patients were quite capable of starting exercises at this period, and I believe that, by getting quickly on to breathing exercises, not only was drainage helped, but the risk of adhesions and pockets forming was much lessened.—I am, Sir, yours faithfully,

CORTLANDT MACMAHON, M.A. Oxf.,
Instructor for Speech Defects and Breathing Exercises at St. Bartholomew's Hospital.

April 7th, 1926.

## PRINCIPALS AND LOCUM TENENTS.

*To the Editor of* THE LANCET.

SIR,—A letter from the Medical Defence Union which appeared in your issue of March 27th has led to inquiries as to the attitude adopted by the London and Counties Medical Protection Society where actions are brought against principals who are members of the Society in respect of the professional work of locum tenents who are not members of the Society.

Several years ago a case of the kind came before the Council of the London and Counties Medical Protection Society and it was undertaken on behalf of the member, although the locum tenent from whose work the claim arose was not a member of the Society. This did not involve any departure from the rule that one subscription should not be allowed to cover the work of two or an indefinite number of practitioners associated as principal and assistant. The Society was advised that a principal is not legally liable for the default of a locum tenent provided he has used proper care to make sure that the locum tenent is properly qualified and competent. The case referred to never went into court, but the Society has ever since undertaken any case of the kind and intends to do so.

The legal position is not as certain as could be wished, but the fact that cases in which the London and Counties Medical Protection Society has challenged legal proceedings have not resulted in proceedings being carried to trial by the other side seems to indicate that the view taken up by the Society of the legal position is well founded. When a case of the kind does come to trial it is more than probable that it will have to be taken to the House of Lords if a final decision is to be obtained, since the cases bearing on the question in the Court of Appeal are somewhat conflicting.

I am, Sir, yours faithfully,
HUGH WOODS,
General Secretary to the London and Counties Medical Protection Society, Ltd.

Victory House, Leicester-square, W.C., April 12th, 1926.

THE SEAMEN'S HOSPITAL.—From the 105th annual report of the "Dreadnought" Hospital at Greenwich, with its branches and convalescent homes, we learn that the re-modelling of the hospital, the erection of a pathological unit, and the provision of new quarters for the nurses are all being taken in hand. When these works are finished the "Dreadnought" will, it is stated, be "one of the most complete hospitals in the country." There are now two resident medical officers, the nursing staff has been enlarged, and the hospital has been recognised as a nurse's training school.

JERUSALEM OPHTHALMIC HOSPITAL.—The report of the Ophthalmic Hospital of the Order of St. John in Jerusalem shows that during the past year activity increased. Perhaps the most remarkable fact brought out is that, although for nearly three months only two British surgeons were on duty, there were more than 81,000 out-patients' attendances and 1107 operations. Light and power have been installed and the X ray department has been in working order for the last six months. 67 per cent. of the patients suffer from trachoma, "and most of the population continue to live under conditions which ensure its spread."

# Obituary.

## SIR HARRY BROOKES ALLEN, M.D. MELB., LL.D. EDIN.,

EMERITUS PROFESSOR OF PATHOLOGY, UNIVERSITY OF MELBOURNE.

Sir Harry Brookes Allen, one of the best known figures in Australian medicine, was born in 1854, the second son of Mr. T. W. Allen, of Geelong, was educated at the Church of England Grammar School and later at the University of Melbourne, and graduated in medicine at the age of 22. His ability and industry secured him the first place amongst his contemporaries both at school and at the University, and after a year's special study in Europe he returned to Melbourne and was immediately appointed assistant to Prof. G. B. Halford, who had held the combined chair of anatomy and physiology at Melbourne since the inception of the medical school. Shortly afterwards a redistribution of the chairs occurred, Halford retaining that of physiology while Allen was appointed professor of anatomy and pathology, a position which he held from 1882 until, and more than 20 years later, Prof. R. J. A. Berry relieved him of his anatomical duties. He was one of the first, if not the first, of the alumni of the University of Melbourne to occupy a professorial chair in his own University; previously the professors were imported from Europe, but the departure in Allen's case was more than justified.

The long tenure of a chair in which the studies of anatomy and pathology were combined is a good illustration of the best medical education of the time, before the growth of bacteriology reached its full importance in the medical curriculum; and at a small medical school, such as Melbourne then possessed, the combination of normal and morbid anatomy in teaching was found very valuable. Allen availed himself of his opportunities to the full, utilising the wealth of autopsic material at the Melbourne Hospital to which, as professor of pathology, he was the pathologist, for the teaching of anatomy as well as pathology. "All old Melbourne students," writes a very distinguished one to us, "will recognise the value of the opportunities they enjoyed to learn anatomy upon the fresh subject as well as in the dissecting room. Allen was a great teacher, if rather formal in methods. He demanded a high standard of effort from his pupils, but they all realised that he, on his part, spared no endeavour to provide them with an adequate training for their future medical studies. As a consequence, every medical student at Melbourne had a sounder basis of anatomy and morbid anatomy whereon to build than, I believe, is usually the case." As the outcome of his work he created the pathological museum of the University, and with a passion for order and arrangement he devoted all his spare time for many years to its enrichment.

The responsibility for both anatomy and pathology in a school of 300–400 students might justly have absolved him from taking an active part in administration, but the exact opposite occurred, for he found time and energy to act for upwards of 30 years as dean of the medical school. Here, like many anatomists before him, he showed an unusual capacity for affairs. Once a line of policy was determined, he was a master at organisation, and if, as a director of academic policy, he was, perhaps, too much influenced by precedent and more inclined to adopt than to adapt, he proved thoroughly successful. Nor were his administrative services confined to the medical school. Perforce, involved in the general administration and policy of the University, he was for many years an active member of the Council, and the governing body recognised in him an untiring and sagacious coöperator.

Allen was by nature a student rather than a discoverer, while his multifarious preoccupations with the teaching of two important subjects, the development of the school and the progress of the University left him little time for research. Nevertheless, his knowledge and experience of morbid anatomy was so comprehensive that if he had devoted some of the time unselfishly spent in public work to recording his observations he would have gained a wide reputation as a pathologist. Most of his observations on morbid anatomy which he did find time to record will be found in the medical journals of Australia and in the proceedings of various Australasian medical congresses. Amongst the more important are a series of papers on the ætiology of arterial degenerations, where he was one of the first to recognise the relation of certain types of degeneration to previous infection with syphilis.

Among his many activities there should be mentioned that he was, in his younger days, the editor of the *Australian Medical Journal*, and for some time honorary secretary of the Medical Society of Victoria. He was a member of the Central Board of Health for a period and also of the Board dealing with tuberculosis in cattle, in connexion with which he was early to perceive the developments that might arise from proper meat inspection followed by cold treatment. In 1908 he was President of the Australasian Medical Congress, and just before the war was appointed a member of the executive committee of the International Medical Congress.

Personally, Allen was formal in manner, always courteous and considerate and a loyal colleague, but outside his family circle there were few who were on terms of intimacy with him. He possessed a phenomenal memory, and could visualise whole pages of books and reports. This enabled him to remember a chain of reasoning where there was no need to follow the details—a very valuable quality in a much occupied man. As dean of the medical school for so many years, it was inevitable that one of his ability, personality, and capacity for affairs should come to exert a powerful influence within the medical profession in Victoria, and, in fact, he was for many years its recognised leader, always maintaining the best traditions. Some two and a half years ago he had a serious cerebral hæmorrhage from which he never completely recovered, since when he had been a complete invalid. He married the daughter of Mr. Henry Mason, of the Liverpool Customs, by whom he had three daughters.

## KATE MARION VAUGHAN L.S.A., D.P.H. CAMB.

WE regret to announce the death on March 29th of Dr. Marion Vaughan (née Hunter) at the age of 61. Dr. Vaughan had been in bad health for some years, but she was reticent about herself, and the news of her death has come as a shock to a wide circle of friends and patients. Marion Hunter was born in Flintshire, one of a family of seven, and was educated at the Blackheath and South Hampstead High Schools. Then, in early womanhood, came the question, in her circumstances inevitable, of a profession, and with the help of her uncle, the late Sir W. Wilson Hunter, she was able to enter the London (R.F.H.) School of Medicine for Women. From every point of view her training was a good investment, for she possessed the gifts and the character required in medical practice. As a student she was prominent in her year; from her earliest days her energy, practical ability, and extreme kindness to those in need of help were conspicuous qualities.

In 1894 she took the L.S.A. and later, from King's College, took the D.P.H. Cambridge. After qualifying she held the posts of clinical assistant and assistant anæsthetist at the Royal Free Hospital, and then, in 1898, went abroad to India and to Egypt, where she did valuable work combating plague in Government service. When she returned to England, she settled in South Kensington and began to build up the large general practice which afforded such a conspicuous testimony to the esteem in which her patients held her. In 1909 Marion Hunter married Percy Cecil Vaughan, barrister-at-law, and the happiness of their brief married life—Mr. Vaughan was killed in the war in 1915—coloured her whole subsequent career. Dr. Vaughan herself worked for a time in France at the Anglo-French Military Hospital, and another side of her war work was the foundation, in 1916, of the West Islington Welfare Centre. In this she had the coöperation of Mrs. Edward Moon. During the ten years which have elapsed since its foundation, the work at this centre has grown steadily from very modest beginnings until to-day West Islington is among the largest welfare centres in London. In addition to the out-patient side, at which last year there were 18,000 attendances, West Islington has from its beginning had a ward with 15 cots for sick and ailing babies, and here, above all, Dr. Vaughan showed her untiring devotion and skill. It was never too late for her to come from the other side of London to see a sick baby, and, indeed, the progress of this centre was one of the keen interests of her busy life.

Dr. Vaughan was eager to keep herself abreast of medical science. She took trouble to obtain special experience, especially in pediatrics, and worked for a time as assistant medical officer to the London County Council. Later she became keenly interested in the recent developments of light treatment, and last year initiated, with others, an artificial sunlight clinic in Mayfair. In everything she did she was quick and practical, wise and prompt in crises, of good judgment, and unfailing kindness to those who sought her help. It is no exaggeration to say that she accepted the troubles of her patients, and took their lives as well as their bodies under her care, in order to bring them into happier as well as healthier ways. Her gallant struggle against ill-health during the last four or five years was unperceived by many of them, so great was her self-control. Dr. Vaughan had an imperious manner, and her abrupt decisions were sometimes disconcerting to her friends, but many patients found in her just those qualities of strength and firmness which they needed for their support in times of trouble. The fact that early financial stress had prevented her from proceeding to take higher degrees and possibly to adopt the life of a consultant was a blessing to the many families who relied on her not only for sound medical advice but for common sense and kindly interest in their daily routine. In Dr. Vaughan Kensington has lost a practitioner of unusual skill and merit.

## FREDERICK WILLIAM AXHAM, L.R.C.P. EDIN.

Dr. F. W. Axham, who died on April 8th at the age of 86, received his medical education at St. George's Hospital, London, and qualified as M.R.C.S. Eng. in 1861; six years later he became L.R.C.P. Edin. by examination. Before settling down in England he saw service in China as surgeon-in-chief to the Franco-Chinese Forces and worked as north district surgeon and sub-immigration agent in British Honduras. Then he came back to London, where he practised for many years in Golden-square, and was medical officer to the Westminster Union Workhouse. In 1905 he began to be interested in the manipulative surgery of Mr. (now Sir Herbert) Barker, and watched him at work on many occasions. He consented to help Mr. Barker in his practice by administering anæsthetics, and during five years no complaint was made against this conduct. In 1911 an action was brought against Mr. Barker for damages, and in the course of the hearing Dr. Axham described his work. This led to his appearance before the General Medical Council in May of the same year, at the complaint of the Medical Defence Union, on a charge of having assisted an unregistered person to practise. Dr. Axham said that he realised that he had not followed the strict rules of the profession and must put up with the consequences rather than give an undertaking not to give anæsthetics for Mr. Barker in future. His name was removed from the Medical Register and his diplomas were withdrawn by the Colleges which had granted them. He continued to help Mr Barker, and in an unsigned letter to the *Saturday Review* (March 24th, 1917, p 270) explained that he was doing what he conceived to be his duty at considerable personal sacrifice

Dr Axham retired from practice some years ago, but it was not until 1025 that any application was made for his name to be replaced on the Medical Register Before the General Medical Council could take action it was necessary that Dr Axham should have one of his diplomas returned to him, and his reinstatement by the Royal College of Physicians of Edinburgh came too late for the Council to consider his application at its last meeting in November

The medical profession has had much sympathy with Dr Axham in the late phases of the contentions around him, though quite aware that the criticisms directed against the General Medical Council were frequently erroneous, and this in quarters where fuller knowledge might have been expected, and where the case was not being used as an opportunity to discredit the medical calling

## GEORGE SHERMAN BIGG, F R C S EDIN

Dr Sherman Bigg, who died on Easter Day in his seventy-first year, was educated at Overslade and Rugby Schools. He was a good athlete and swimmer and was captain of Fives at Rugby He studied at the Middlesex Hospital and became L.S.A. in 1876, M.R C.S in 1877, and F R C S Edin. in 1888 He joined the Army Medical Service and served as staff surgeon under General Macpherson at Allahabad and later at Dover, and also throughout the Egyptian campaign. On leaving the army he settled in practice in Victoria-street, Westminster Ill health compelled him to retire in 1028, and he suffered much up to the date of his death. He wrote a number of papers on hygiene in the tropics and child welfare

## HAROLD TURNER FINLAYSON, M B ,
## CH B ABERD

Dr H. T Finlayson, who has died at Formby, Lancashire, at the early age of 36, was the eldest son of Mr Boyd Finlayson, clerk to the Aberdeen Educational Authority, and had been in practice at Formby for about ten years He was educated at Aberdeen and at St Mary's Hospital, London, where he acted as casualty officer after graduating in 1912 After holding a number of house appointments in Dundee and elsewhere and spending some time as ship's surgeon in the East, Dr Finlayson saw service in the early days of the war with the Grand Fleet, and later held a commission in the R.A.M.C Settling in practice at Formby he kept in touch with many of the special departments of medicine and surgery, and was appointed clinical assistant in the Royal Southern Hospital, Liverpool, medical officer of the Holmewood School and Children's Sanatorium, Freshfield, and neurologist to the Ministry of Pensions The self-sacrificing way in which he did his work led him to overtax his strength Dr Finlayson had many and varied interests—athletic, social, artistic—and to any particular case in which he was engaged he brought a human touch, a sense of sympathy, and a hopeful outlook which made his services especially helpful

THE LATE DR. H T PRINGLE.—At the age of 85, Dr Henry Turnbull Pringle died on March 30th at Ferndown, Dorset, where he had been living for some years past. He was born in Roxburghshire and graduated in medicine at the University of Glasgow with first-class honours in 1800, proceeding to the degree of M D two years later On qualification he was appointed medical officer to the Glamorgan County Mental Hospital at Bridgend, and later became medical superintendent there In 1004 he relinquished the position, but retirement did not mean inactivity He was made a justice of the peace for Dorset in 1010 and three years later was appointed a member of the advisory committee for the appointment of magistrates in the county

# Medical News.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE: *Course in Physiology Applied to Hygiene.*—With the concurrence of the King's College Delegacy, Prof R J S. McDowall will deliver at the School a course of lectures, commencing May 7th, in physiology applied to hygiene. The course is primarily intended for students preparing for the diploma in public health, and the lectures are being given in pursuance of the policy of the Board of Management of supplementing, where necessary, the facilities for teaching for the D.P.H. available at other institutions, pending the development of the full scheme of teaching when the new school is ready In these lectures will be given the more modern aspects of those parts of physiology which form the basis of public health work and which are not yet easily available in book form. The syllabus of lectures is as follows:

1 *General.*—The body as a physical and mental machine, its relation to environment. The principles involved in promoting efficient longevity in a certain sphere

2 *Physical Work*—The response of the body to physical exercise. Its relation to health and to artificial exercises. The influence of use and disuse. Physical standards.

3 *Mental Work and Associated Phenomena*—The nervous system and the general principles of its function. Habit formation some aspects of psychology The influence of use and disuse.

4 *Fatigue and Overstrain.*—Muscular fatigue mental fatigue. Recovery The importance of sleep, variety interest, and alternation.

5 *Industrial Fatigue.*—Applications of the foregoing The sense of well being. Vocational tests, their principles, practice, results.

6 *Digestion.*—General principles with special reference to the prevention of common ailments—e.g. indigestion, constipation, &c. The relationship of physical and mental states.

7 *Metabolism and Growth General Principles of Metabolism.*—Diet, endocrines, vitamins in their relation to growth. Basal metabolism

8 *Body Temperature and Water Content.*—Their maintenance and relation to environment.

9 *Effect of Open Air and Sunlight*—Relation to vitamins.

10 *Principles of Respiration, with Special Reference to the Effect of Various Gases and Abnormal Pressures*

11 *Normal Protection of the Body against Disease.*—Skin, lymphatic tissue, digestion, excretion, immunity in their more physiological aspects. Their relation to water-supply, exposure to cold, &c.

12 *The Child.*—General care, speech, intelligence tests, evidence of deficiency

For the present no fee will be charged to D.P H. students Inquiries should be addressed to the Secretary of the School

ROYAL SANITARY INSTITUTE —A sessional meeting will be held in the Guildhall, Hull, on April 23rd and 24th, when there will be discussions on Housing, on the Public Health Functions of Bodies other than the Sanitary Authority (Dr W Allen Daley and Dr J J. Buchan), the Economic Collection of Town Refuse, and the Present Position with regard to Smoke Prevention.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —Mr Herbert J Paterson will give a demonstration in clinical surgery at the London Temperance Hospital on Thursday, April 22nd, at 2 P.M., which will be free to members and General Course ticket-holders of the Fellowship of Medicine The Bolingbroke Hospital will hold a short course in medicine and surgery from April 19th to May 1st, the fee for which will be one guinea. Also beginning on April 19th there will be an intensive one week's course in proctology at St. Mark's Hospital and a two weeks' course in urology at St. Peter's Hospital, consisting of clinical work in the hospital daily and formal lectures. From May 3rd to 22nd a special course in medicine, surgery, and gynæcology will be held at the Royal Waterloo Hospital The Central London Throat, Nose and Ear Hospital will hold an intensive course in laryngology, rhinology, and otology from May 3rd to 22nd. This will be divided into clinical and operative parts; the parts may be taken separately if desired. The Royal Westminster Ophthalmic Hospital is holding an afternoon course from May 3rd to 22nd, with clinical work each afternoon and special demonstrations thrice weekly A comprehensive course in Venereal Diseases will be given at the London Lock Hospital from May 3rd to 29th. The clinical part of the course will be held irrespective of numbers, but the formal lectures will only be delivered if there are eight or more entrants. At the Maudsley Hospital there will be a course of lectures and demonstrations in Psychological Medicine from May 3rd to 28th; this is an abridgement of the diploma course now in progress there From May 9th to 22nd the Infants Hospital will give a course under the direction of Dr Eric Pritchard. Copies of all syllabuses, of the General Course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

UNIVERSITY OF LONDON.—A course of four lectures on the Integration of the Circulation will be given by Prof. R. J. S. McDowall at King's College, on Tuesdays, April 27th, May 4th, 11th, and 18th, at 4.30 P.M.; Prof. Kay Jamieson will lecture at King's College on the Nature and Functions of the Fasciæ of the Human Body on Fridays, April 30th, May 7th and 14th, at 5.30 P.M., and Prof. J. B. Collingwood will give the remaining lectures of the course on the Influence of Water on Vital Processes at University College on Mondays, April 26th, May 3rd, 10th, 17th, 24th, and 31st, at 5.30 P.M.

ROYAL MEDICAL BENEVOLENT FUND.—The date of the annual meeting will be Tuesday, April 20th, and not April 22nd as was previously announced. The meeting will be held at 11, Chandos-street, London, W., at 5 P.M.

THE LATE DR. W. K. LAW.—Dr. William Kidston Law, brother of the late Mr. Bonar Law, has died at his home at Coleraine, Co. Londonderry, at the age of 73. He was born in New Brunswick, the son of a Presbyterian minister, and studied at McGill College, Montreal, where he graduated as M.D., C.M. in 1877. He crossed the Atlantic as a young man and settled in practice at Coleraine, after taking the Scottish conjoint qualification; in 1884 he became F.R.F.P.S. Glasg. Dr. Law was well known as a breeder of Irish horses and was a large stockowner. His only son, Mr. James Law, has lived in Canada for the last 20 years.

INSTITUTE OF JOURNALISTS.—A meeting of the Circle of Scientific, Technical, and Trade Journalists will be held in the Hall of the Institute on Monday, April 19th, at 5 P.M., when Mr. J. G. Pearce (chairman of the Committee of the Association for Special Libraries and Information Bureaus) will open a discussion on a Clearing House for Information; its Value to Science and Industry, and its Relation to the Press. Those intending to be present should inform Mr. L. Gaster, 32, Victoria-street, London, S.W. 1.

PLAGUE IN INDIA.—The Bulletin of Health for the City of Bombay for February, 1926, records nine deaths from plague registered in February and two in January, the average number of deaths in February during the last ten years being 61. Calcutta was needlessly alarmed by the Weekly Bulletin of Vital Statistics issued for the week ending March 6th, 1926, which stated that "there were 20 deaths from plague against nil and nil in the two preceding weeks, the average of the past quinquennium being nil." We understand from Dr. H. M. Crake, health officer to the Calcutta Corporation, that 20 was a misprint for NO, and, in fact, that Calcutta has been absolutely free from plague since Dec. 7th, 1925.

ST. MARY'S HOSPITAL.—The Institute of Pathology and Research at St. Mary's Hospital, London, W., is holding a course of lectures on Pathological Research in its Relation to Medicine, which will be held in the Bacteriological Department on Thursday afternoons at 5 P.M., beginning on April 29th, when Sir Almroth Wright will speak on the General Outcome of Thirty-six Years' Work on Immunisation. The other lecturers will be Prof. Joseph Barcroft, Dr. Leonard Colebrook, Prof. J. Mellanby, Prof. David Wilkie, Dr. Charles S. Myers, Dr. John Freeman, and Mr. J. E. Barnard. The lectures will be open without fee to members of the medical profession and students of medicine.

THE LATE DR. J. JARVIS.—Dr. John Jarvis, who died on March 27th at the age of 66, had practised in Bath for 33 years. He studied medicine at St. Thomas's Hospital, London, and qualified as M.R.C.S. Eng., L.R.C.P. Lond., in 1885. For some time he worked at Liverpool as surgeon to the Liverpool Dispensary, and at Abingdon as surgeon to the Lying-in Charity. Dr. Jarvis first went to Bath as partner to the late Dr. John Davies and was later for a time in partnership with Dr. F. C. Fosbery. He had a large panel practice and for some 30 years was surgeon to the Western Dispensary. He was also honorary surgeon to the Church Army Labour Home. He married the sister of Dr. Fosbery and leaves one son and two daughters.

LONDON COUNTY COUNCIL: APPOINTMENT OF A FIFTH SENIOR MEDICAL OFFICER.—At a meeting of the Council held on Feb. 9th last it was decided to increase by one the number of positions of senior medical officer in the public health department, and 67 applications for the new position were received after it had been advertised. The selected officer is Dr. Aubrey Middleton Hewat, at present medical officer of health and administrative tuberculosis officer for the Metropolitan Borough of Fulham, which has released him to take up his appointment in a month's time, remaining honorary consulting medical officer to Fulham for two months after the date of his leaving office there. Dr. Hewat is an Edinburgh graduate who was medical officer of health for Nuneaton and Preston before being appointed to Fulham.

## NOTES ON CURRENT TOPICS.

### FACTORY MEDICAL SERVICE.

To the debate on the motion for the second reading of the Labour Party Factories Bill in the House of Commons on March 26th, as yet unreported in these columns, important contributions were made by medical Members of the House.

### *The Home Office Staff.*

Dr. VERNON DAVIES said that factory legislation being concerned principally with the health of the people and the prevention of accidents, it seemed to him that one of the most important servants of the State to carry out this legislation should be the factory surgeon. He had a knowledge of medical matters, of industrial hygiene, and of accidents. He regarded the medical man, the certified surgeon, as the sheet anchor and the most important man in factory legislation because he had to decide what was best for the worker. Yet they found that the Home Office—he said this with due respect—which exercised a very great amount of control over factory legislation did so without giving the fullest attention to the medical aspect of the case. They knew that the Home Office had an extremely able medical staff of eminent men who were at the head of the profession, but they wondered sometimes whether the Home Secretary paid as much attention to the recommendations of his medical staff as he should do. It had been said that some certified surgeons had been incompetent and neglected their work. He would draw attention to the fact that the present Chief Medical Inspector, who was an eminent man, spent the greater part of his official life until the war in attending to industrial diseases and poisoning. It was only just before the war that he devoted his attention to examinations for fitness. Since that time the work of the examination of children had improved tremendously in quality and had kept on improving. Provided that the certified surgeon got proper encouragement and proper opportunities for inspections he had no fear that the factory medical service would not reach a high standard of efficiency. But in this Bill the certified surgeon was put into an absolutely new category. Instead of being made centrally from headquarters the appointment was proposed to be made locally. Instead of having one certified surgeon they might have six or seven surgeons doing factory work, either at the instance of the Home Secretary or the local authority.

The argument had been used that it was better that the factory health service should be linked up with the local medical service. He disputed that statement. They all knew that at the present time the position of a medical officer of health was largely a local appointment made with the Ministerial sanction, but it was well known that they might have two urban district councils close together where the appointments were practically made locally without great regard for efficiency, and that in one urban district council area they found a medical officer who was keen at his work, while in the next district council area they found a condition of things which was just the reverse. That was a very great objection to local appointments. On the other hand, they found that for many years the certified surgeon had been regarded as a Government officer both by the employers and the workpeople. He had gone to the factory with a certain amount of independence not subject to local influences, and the mill authorities had paid much more attention to his decisions than they would have done had he been appointed locally with the possibility of being dismissed through local intrigue and influence. They had to recognise that certain suggested improvements in factory legislation did not always meet with the approval of the employers. If they thought that a man was going to be too officious and too anxious to bring conditions up to a high standard they might be able to bring pressure to bear and perhaps in extreme cases get rid of that man. That would not be wise, and he believed that this alteration had been put into the new Bill—namely, the substitution of appointed doctors for certifying surgeons—probably because of the report of the Committee on the Medical Examination of Young Persons in Factory Employment instituted by Mr. A. Henderson. On that committee there was no medical man of actual experience in factory work. When Mr. Henderson was asked to include such a member he replied to the Association of Certifying Surgeons that the committee had already been formed after careful consideration and that such a gentleman could not be added to the committee. Only one doctor of practical experience in this work had been called before the committee to give evidence, and the doctors thought that the committee had not that full knowledge of the case for the certifying surgeons which the circumstances warranted, and that if medical men accustomed to factory work had been on the committee the report would have been different.

There was a danger that there would be no agreement between the different districts and uniformity would be impossible. The importance of this point to the workers was very great, because if they were to have an efficient factory service worked on definite lines they should have a sufficiency of medical inspectors—there were only two at present—to go all round the country to see that the certifying surgeons were all working on the same lines and to the same standard of efficiency. In that way they would get an admirable service with such wonderful effects on the workers and on industry that it would more than repay itself. He hoped that the Home Secretary in his promised Bill would give careful consideration to this question of the certifying factory surgeons and as to whether the present system was best. No doubt there were some men who did not take their work as seriously as they should, but there had always been a large number of conscientious and able certifying surgeons. It was essential for the good of industry and of the worker that this factory service should be worked from above and by Government officials under the Home Office and that standardisation throughout the country should be insisted upon. Medical men then would take an interest in what they had to do, to the benefit of all concerned.

### *The Certifying Surgeon.*

Dr. Watts said while he agreed that reform of the factory law was necessary he joined with Dr. Vernon Davies in taking exception to the attack made upon the Association of Certifying Factory Surgeons. As an ex-President of that Association and as one who for 25 years was a certifying surgeon in the industrial district of Manchester, he claimed to have a long knowledge of the work of certifying surgeons, and though they had been hampered and discouraged by the department time after time yet for a great number of years their work had been steadily improving. He would mention particularly those surgeons with districts of any size. There were roughly 1800 certifying surgeons in the country, but only 250 had a district that entailed the examination of more than 50 or 60 children per annum. With the work of the 1500 or more who had a small district he was not acquainted, but as to the work of the 250 members of the Association of Factory Surgeons he could speak with confidence of the excellent official work they had done, while in addition they had instituted many reforms and health improvements in the industrial system. For example, there was their work in connexion with the prevention of lead poisoning and carbon bi-sulphide poisoning and other industrial diseases which were now practically dying out. He had been interested for many years in a matter which was a great danger in the cotton industry—namely, the threading of shuttles by suction. A departmental committee was appointed, but nothing had been done. He had seen very definite instances of people who had contracted tuberculosis in this way. He urged that in the forthcoming Bill which the Home Secretary had promised to introduce this session they should have a unification of the factory medical service. This had already been recognised by Belgium, Holland, and Sweden. In each of those countries there was at present a complete factory medical service which was founded largely on the recommendations of the Association of Factory Surgeons in this country. He believed that they could get together in Great Britain the finest factory medical service in the world. There was an important point he wished to refer to, and that was in regard to the duties which the certifying factory surgeon had to perform in connexion with the Workmen's Compensation Acts. In the case of a workman suffering from one of the scheduled diseases, such as lead poisoning, it was first necessary for the person who was suffering to get a certificate from the certifying surgeon prior to any compensation claim. If the certifying surgeon was appointed by the local council what was going to be his position having regard to the fact that in many cases the employer might be a member of that local body? The workman, too, might be a member of it. Up to now the certifying surgeon had been an independent official, and the point was one which ought not to be lost sight of.

### *Unification of Health Service.*

Lieut.-Colonel Fremantle said that everybody would recognise that from the point of view of medical officers of health and inspectors a Bill of this kind should be passed into law as soon as possible. There were, however, very serious reasons from the point of view of those who envisaged public health as a whole why the House should not accept this Bill as it stood at present. They would not get the things set right of which they had heard in that debate unless they had continuous supervision. The certifying factory surgeon would have to certify, and was not there to watch the processes and see where medical science could help. They needed an authority at the head who was constantly there to help. At present it was left to the non-medical inspectors. They had to consider this matter a good deal more clearly than they had done at present to see in what way they could get some unity of effort between all the different conflicting medical officers and sanitary authorities and education authorities who were brought into this Bill in order that there might be a combination of effort to improve the health of the country and health in our factories. He did not suggest that the whole of the health side of the Home Office should be transferred to the Ministry of Health; that was a big question and he did not agree with it, but he did say that if the Ministry of Health was to be worthy of its name it must be in active and direct liaison with the carrying out of the Factories and Workshops Acts.

## HOUSE OF COMMONS.

### Tuesday, April 13th.

### The Economy Bill.

The House reassembled after the Easter recess on April 13th, and went into Committee on the financial resolutions connected with the Economy Bill. Mr. J. F. Hope was in the chair.

### *Health Insurance in the Services.*

Sir L. Worthington-Evans (Secretary of State for War) moved a financial resolution which in conjunction with another resolution empowered the Government to take £1,100,000 from the Navy, Army, and Air Force Insurance Fund. He said that the only effect would be to enable members of the fund to obtain benefits in addition to those provided by the Insurance Act and to call on the State to contribute one-seventh of the cost of those additional benefits. Under the existing provisions of the Insurance Act serving soldiers, sailors, and airmen paid nothing so long as they were in the forces, but the War Office made a contribution to the Insurance Fund which enabled the Service men to receive only maternity benefit while serving. A separate Army, Navy, and Air Force Insurance Fund had been set up for the benefit of the men whose health had been impaired through their service and whom no society would accept as members. Members of this fund were only entitled to standard benefits and not to any additional benefits. The alteration now proposed would give members of the fund the right to receive additional benefits equal, on the average, to the average benefits payable by the approved societies. The Government Actuary's report stated that there was a surplus, on Dec. 31st last, of £1,121,000 on the Army, Navy, and Air Force Insurance Fund, after providing for ordinary benefits. It was now proposed to transfer £1,100,000 of the surplus and to leave the balance in the fund. The Actuary advised that that amount would be sufficient to enable the fund to bear the additional benefits. This part of the Economy Bill would undoubtedly give greater benefits to the serving soldiers, sailors, and airmen than before. This money was not a surplus available for additional benefits, and if it was not transferred under the Bill it would be used to lower the Government's contribution and the men would not receive it. The Government were taking every precaution that the fund should be solvent on their Actuary's advice.

After a prolonged discussion in which Mr. R. J. Davies and Sir John Simon took part, and Mr. Lloyd George said that there was no distinction between the Government's proposals and the raiding of a bank or a public company, the resolutions were agreed to.

### *Cost of Medical Benefit.*

Clause 2 of the Economy (Miscellaneous Provisions) Bill provides that:—

> (1) Subject to the provisions of Section 83 of the principal Act there may out of the benefit funds payable under that Act be applied for the purpose of meeting the cost of medical benefit, the administration expenses of insurance committees, and any expenses incurred by the Minister in connexion with the administration of benefits, a sum at such yearly rate as may be prescribed, not exceeding 13s. per year in respect of each of the total number (calculated in the prescribed manner) of the persons who are entitled to medical benefit as being or having been members of an approved society, and there shall be paid for each year to insurance committees on account of the cost of medical benefit and their administration expenses, and to the Minister on account of expenses incurred by him in the administration of benefits, sums not exceeding in the aggregate the sum applicable as aforesaid, and not exceeding as respects the administration expenses of insurance committees the sum of sixpence, and as respects the expenses of the Minister the sum of threepence, in respect of each of the total number aforesaid: provided that if the aggregate sum paid for any year to insurance committees and the Minister under this section in respect of each of the total number aforesaid is less than the sum applicable as aforesaid in respect of each of the total number, the balance shall be carried forward and be treated as being applicable as aforesaid in any subsequent year.

(2) For the purpose of meeting any additional expenditure which may be incurred in the provision of medical benefit in Wales by reason of sparsity of population or difficulty of means of communication, provision may be made by regulations for the payment out of the National Health Insurance Fund to the Welsh National Health Insurance Fund of such sum as may be prescribed.

(3) This section in its application to Scotland shall have effect subject to the following modifications: (a) In addition to the payments to be made under Subsection (1) of this section out of the sum applicable as provided by that subsection, there may be paid thereout any expenses of the Scottish Board of Health in connexion with the provision of a medical service for insured persons in such districts of Scotland (other than the Highlands and Islands within the meaning of the Highlands and Islands (Medical Service) Grant Act, 1913) as may be determined by the Board to be necessitous, and references in the said Subsection (1) as applied to Scotland to expenses incurred by the Board shall be construed as including the expenses aforesaid; and (b) the maximum sums as respects the administration expenses of insurance committees and the expenses of the Board shall be such sums as may respectively be prescribed.

(4) This section shall come into operation on Jan. 1st, 1927.

### *An Amendment.*

Mr. R. J. DAVIES moved an amendment to omit the provision that any expenses incurred by the Minister of Health in connexion with medical benefit should fall on the approved societies. He said that the purpose of the amendment was to challenge the power of the Minister in this matter. The Minister made agreements on behalf of the insured population with general practitioners acting as panel doctors, and the Opposition were not quite satisfied that the right hon. gentleman had so far made, or would in future make, the best bargain possible with the doctors in favour of the insured persons. There was a great deal of criticism, not of the attitude of the Minister of Health, but of the actions of the medical profession in giving treatment to insured persons. For his own part, on the whole, he thought that the panel doctors had done their work admirably under the State insurance scheme. He believed, however, that the doctors had been paid handsomely for their work and that the Minister had not been at all stingy with them. The Minister should pay more attention to the opinions of the approved societies and his power to veto their proposals should be taken away. The cost of administration ought to fall on the Exchequer.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that the provisions of Clause 2 of the Bill were designed to carry out the recommendations of the Royal Commission on National Insurance. The Commission came unanimously to the conclusion that medical benefit should be paid for out of the funds of the approved societies. The whole of the clause had received the support of the Consultative Council.

Mr. R. J. DAVIES asked whether the support of the Consultative Council in regard to Clause 2 of the Bill was not contingent on the omission of Clause 1.

Sir KINGSLEY WOOD said that that was not so. The Treasury would save, by the proposal, 3*d.* per member per year in respect of the cost of regional medical officers and of the Central Index Register.

The amendment was rejected by 208 votes to 140—Government majority 68.

### *Registration of Optical Practitioners.*

Mr. KELLY asked the Minister of Health what action he proposed to take to meet the views expressed by the recent deputation from the joint council of qualified opticians with regard to the practice of sight-testing; and what was the attitude of the Government with regard to the proposed Bill for the registration of optical practitioners.—Sir K. WOOD replied: For reasons explained to the deputation referred to by the hon. Member my right hon. friend does not propose to take any action in the matter and the Government are not prepared to grant any facilities for the passage of the Bill.

### *Accidents Due to Splintered Glass.*

Colonel DAY asked the Minister of Transport whether he was aware of the number of accidents lately to public service vehicles in which passengers had been injured by splintered glass; and would he consider the advisability of enforcing the fitting of non-splinterable glass in all passenger-carrying vehicles in the future.—Colonel W. ASHLEY replied: With regard to the first part of the hon. and gallant Member's question, I have no information. With regard to the second part, I am anxious to encourage the use of some form of unsplinterable glass on public service vehicles, but I am advised that, for reasons of cost, it would not, for the present, be practicable to make its use compulsory.

# Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

## SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, April 20th.—5.30 P.M., General Meeting of Fellows. Ballot for election to the Fellowship.

THURSDAY.—8.30 P.M., UROLOGY. Clinical and Pathological Meeting.

FRIDAY.—4.30 P.M., STUDY OF DISEASE IN CHILDREN. Clinical Meeting at the Hospital for Sick Children, Great Ormond-street, W.C. 8 P.M., EPIDEMIOLOGY AND STATE MEDICINE. Sir Leonard Rogers: The Climatic and Other Factors Influencing the Spread of Cholera in India.

THE MEDICO-LEGAL SOCIETY, 11, Chandos-street, W.

TUESDAY, April 20th.—8.30 P.M., Mr. C. Ainsworth Mitchell: Some Aspects of the New Regulations on Preservatives, followed by a discussion.

CHELSEA CLINICAL SOCIETY.

TUESDAY, April 20th.—8.30 P.M. (in the Board Room of St. George's Hospital), discussion on the Treatment of Late Syphilis. Speakers: *Prof. J. Eyre and Dr. C. E. Sundell.*

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, April 19th, to SATURDAY, April 24th.—Special afternoon demonstration in clinical surgery on Thursday at 2 P.M. by Mr. W. E. Tanner at the Prince of Wales's General Hospital, Tottenham. Open to all members of the Fellowship and to General Course ticket-holders.—ROYAL FREE HOSPITAL, Gray's Inn-road, W.C. Wednesday, 5.15 P.M., Dr. Heald: Demonstration on the Diathermy Current—its Uses and Application (part of special course).—ST. MARK'S HOSPITAL, City-road, E.C. Intensive course for one week.—ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, Great Portland-street, W. Intensive course (second week). —ST. PETER'S HOSPITAL, Henrietta-street, W.C. Clinical course every afternoon and formal lectures. Further information from the Secretary of the Fellowship of Medicine.

ANCOATS HOSPITAL POST-GRADUATE LECTURES, Quay-street.

THURSDAY, April 22nd.—4.15 P.M., Dr. Langley: Diabetes in General Practice.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, April 20th.—4.15 P.M., Mr. A. H. Burgess: Acute Intestinal Obstruction.

FRIDAY, April 23rd.—4.15 P.M., Dr. F. E. Tylecote: Demonstration of Medical Cases.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES POST-GRADUATE COURSE.

THURSDAY, April 22nd.—4.30 P.M., Dr. Dyson: Eczema.

# Appointments.

BULMAN, J. R., M.B., Ch.B. Edin., has been appointed Medical Superintendent, Burgh Isolation Hospital, Hereford.

CAVE, E. H. P., M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., D.M.R. & E. Camb., Medical Officer in Charge of X Ray Department, Royal Berkshire Hospital, Reading.

NISBET, B. R., M.B., Ch.B. Edin., Assistant Medical Officer and Assistant School Medical Officer, South Shields.

# Vacancies.

*For further information refer to the advertisement columns.*

*Belfast, Mater Infirmorum Hospital (Incorp.).*—Hon. Asst. Gynæcologist.

*Bethlem Hospital, Lambeth-road, S.E.*—Res. H.P. £25 per quarter.

*Birkenhead Education Committee.*—Asst. M.O. £600.

*Bradford Royal Infirmary.*—H.S. and H.P. Each £150.

*Bristol Royal Infirmary.*—Hon. Asst. Surg.

*Burton-on-Trent Infirmary.*—Jun. Res. H.S. £150.

*Carshalton, Surrey, Queen Mary's Hospital for Children.*—Asst. Bacteriologist. £600.

*Chester Royal Infirmary.*—Third H.S. £150.

*Coventry and Warwickshire Hospital, Coventry.*—Res. H.S.'s £150. Res. H.P. £125.

*Eastbourne, Princess Alice Memorial Hospital.*—Res. H.S. At rate of £175.

*East London Hospital for Children.*—H.P. and Cas. O. Each £125.

*Foot-and Mouth Disease Research Committee.*—Two Research Assts £500
*Gloucester County Mental Hospitals, Wotton and Barnwood.*—Jun. Asst. M.O £350
*Gordon Hospital, Vauxhall Bridge-road, S W.*—Res. H.S. £75
*Greenwich, Dreadnought Hospital.*—Med. Supt. £300.
*Leicestershire County Council*—Asst Tuberculosis M.O £600
*Liverpool, Alder Hey Children's Hospital, West Derby*—Res. Asst. M.O £200
*Liverpool, Eye and Ear Infirmary, Myrtle street.*—Hon. Aural S.
*London Hospital, E*—Asst. in Dept. of Dermatology and Syphilology
*Macclesfield General Infirmary*—Second H.S £150
*Maudsley Hospital, Denmark Hill, S.E*—Research Fellowship in Psychiatry £300
*Metropolitan Asylums Board, Colindale Hospital, Hendon, N W*—Jun. Asst. M.O £500
*Metropolitan Asylums Board, Grove Park Hospital, Lee, S.E.*—Sen. Asst. M.O £650
*Newcastle-upon Tyne, Royal Victoria Infirmary*—Surg Reg to Throat, Nose and Ear Dept and Surg Reg to Ophthalmological Dept. £100
*Nottingham, Children's Hospital.*—Res. H.S. At rate of £150
*Plymouth Borough*—Asst. Port M O &c. £750
*Preston and County of Lancaster Royal Infirmary*—Jun. H.S. £150
*Royal Free Hospital, Gray's Inn road, W C*—Gynæcologist.
*Stockton and Thornaby Hospital, Stockton-on Tees.*—Jun. H S. £200
*Surrey County Council, Kingston-on Thames.*—Asst. M.O £600
*Walthamstow, Wanstead and Leyton Hospital, Orford-road, E*—Jun H S. At rate of £100
*Winchester, Royal Hampshire County Hospital.*—H.P At rate of £150

# Births, Marriages, and Deaths.

## BIRTHS

DUNCAN—On April 6th, at Gay-street, Bath, the wife of W H. Duncan, F R.C.S., of a son.

GALBRAITH.—On April 6th, at Woodside-terrace, Glasgow, the wife of Walter Weir Galbraith, M.B., Ch.B, of a daughter

PARRY—On April 2nd, at Brynhyfryd, Pwllheli, to Dr Joan, the wife of Dr R. H Parry—a daughter

SCOTT—On April 5th at Bockum, Potter's Bar, the wife of Dr. J M. Duncan Scott, of a daughter

## MARRIAGES

ARTHUR—SADLER PHILLIPS.—On April 7th, at St. Mary's Church, Wimbledon, David Arthur, M.D., C.M., D.P H, to Mabel, widow of John Sadler Phillips, late Vicar of St. Matthew's, Ealing Common.

BICKERTON—HAWDON—On April 10th, at St Cuthbert's Church, Ormesby, John Myles Bickerton, F R.C.S. Eng, to Margaret Alsager, only daughter of Colonel and Mrs. Hawdon, of Nunthorpe, Yorkshire.

RAWSON—BROWN—On April 8th, at St. Maxentius, Bradshaw, Lancashire, Lieutenant Selwyn G. C. Rawson, R.N (retd.), to Doris Brown, M.B., Ch.B., D.P.H

WHITEHEAD—BAKER.—On April 6th, 1920, at St. James' Episcopal Church, Aberdeen, by the Rev Canon Bartlet, M.A., Rector, Gordon Whitehead, M.B, Ch.B, of Athol Villa, Dukinfield and 6, St. Ann's Passage, Manchester, to Mary Gertrude (Mollie) younger daughter of J. W Baker Esq, J P., and Mrs. Baker, of 14, Albert-street, Aberdeen.

## DEATHS

AXHAM.—On April 8th, at Kilmartin-avenue, Norbury, Frederick William Axham, L.R.C.P, aged 86

MARTIN—On April 5th, after three days' illness of pneumonia, at Oriel House, Abingdon, Paulin John Martin, M.R.C.S., L.R.C.P

RAIKES.—At Midland, Ontario, Canada, on April 7th, Lieut Colonel Richard Raikes, O B E., M.D., aged 67.

*N.B—A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths*

## THE LANCET: SUBSCRIPTION RATES.

# Notes, Comments, and Abstracts.

## SOME CURIOSITIES OF CLINICAL MEDICINE.

BY C E. SHELLY, M.D CAMB, M R C.P. LOND.

### II.*

### COINCIDENT DISEASES: THEIR MUTUAL EFFECTS. INFLUENZA AND VARICELLA.

IN those exceptional instances in which two separate and distinct infectious maladies are running their course in the same individual, some modification of one or other is not infrequently to be observed. The most striking cases in which I have noticed this have occurred in the coincident examples of varicella and influenza.

In a family of five daughters, the four elder ones successively developed influenza (then prevalent in the neighbourhood) at intervals of exactly 13 days. There appeared to be nothing in their habits or mode of life to account for this special period of incubation. They had studiously abstained from attending church or any form of social gathering from the time when the first case occurred But, while I have noted cases of acute influenza which developed definite symptoms within a few hours after well-established exposure to a virulent case of the disease, I have also noted others in which the incubation period appeared to be precisely 13 days. All these four cases were of medium severity and pursued the usual course

The fifth and youngest daughter was at a boarding school near London. On the day following that on which the last of her four elder sisters developed influenza she returned home owing to her school having broken up in consequence of a widely spread epidemic of chicken pox. Thirteen days after reaching home she developed influenza. I saw her on the following morning, when my attention was called to the existence of an eruption of minute, slightly raised, macular spots, which were most numerous on the back, at the base of the neck, and especially between the shoulders; there were a few lower down on the back as far as the buttocks, and a still smaller number irregularly scattered about the face, the temples, and the scalp Within 24 hours a few more appeared on the front and sides of the chest, the flanks, and the abdomen.

Viewed through a good reading-glass the eruption was strikingly like the eruption of chicken pox in its earliest stage. It appeared on the morning of the 18th after the patient's last contact with a school fellow whose chicken pox eruption definitely developed the same evening But, in this case, the modified eruption of varicella—as I took it to be—consisted of minute spots, not more than ½ to 1 mm. in diameter, with the exception of one on the right temple, which was 2 5 mm. across when fully developed, corresponding to the popular "king pock." All the spots went through the regular successive stages of macule, papule, vesicle, and mild pustulation—as viewed through a good magnifying glass—and then speedily dried up with a resultant minute scab barely recognisable as such; with the exception of the relatively large spot on the temple, which, on the separation of its scab, left a faintly foveated scar The only discomfort of which the patient complained was of some slight and occasional irritation of the skin during the first two or three days of the eruption. Unlike her four elder sisters, this patient had not previously suffered from chicken pox.

During the later autumn of the same year several similar cases came under observation in a preparatory school of some 50 boys whose ages varied from 9 to nearly 15 years. Epidemics of both varicella and influenza were running in the neighbourhood, and both maladies invaded the school. Anything like rigid isolation of the cases was impossible. Nineteen of the boys were said to have had had chicken pox in earlier life, but the diagnosis was admittedly doubtful in the case of one of them, who developed chicken pox but escaped influenza (from which he had suffered during the previous term) The other 18 developed influenza but did not have varicella. Of the other 30 boys all but three developed influenza, not of a severe type, and 12 of them developed chicken pox also. In eight out of the 12 the two diseases were coincident, that is to say, they developed within two or three days of each other in the same individual; and in each of these eight "coincident" cases, the character and progress of the varicella eruption repeated in every essential particular the details already mentioned as having been noted in the case first described.

It would appear, therefore, that when influenza and chicken-pox occur simultaneously in the same individual, the normal eruption attending the *latter malady is liable to be remarkably* modified, in young adolescents at all events. Assuming that there may be some ancestral kinship between varicella and variola, one would like to know (1) what happens as regards the character of the eruption when variola and influenza occur coincidently; and (2) what effect (if any) would be produced in the small-pox patient by treating him with an influenza serum or vaccine at the beginning of his illness. If the result were no more than a cosmetic gain (and one might reasonably look for more than this) it would be a valuable one.

---

* Part I. appeared in THE LANCET last week.

### Chronic CO Poisoning.

A young woman consulted me on account of neurasthenic symptoms from which she had been suffering through the colder periods of the previous 18 months, during which she had been employed as a typist in a factory situated in a small village amid country surroundings some miles distant. During the summer she recovered her usual good health; even in the colder weather she improved considerably during the week-ends, which were spent at her home, only a short distance from her place of work; but she began to "run down" as soon as she returned to her duties, and at the end of the week felt fit for nothing. Her hours of work were not unduly long. Her eyesight was good, and, save for a markedly anæmic condition, examinaton did not reveal any definite sign of bad health. Her family history was good.

In reply to my questions she stated that during the warmer parts of the year she did not suffer; windows were all kept open and there was no stuffiness. But as soon as a lower temperature called for artificial heat and windows and doors were kept closed the trouble began. The building was lofty, of one floor only, and was not crowded; it was constructed almost entirely of wood. It was heated by a number of iron stoves placed at intervals along one side, the chimney of each being carried up through the roof. Her desk was not far from one of these stoves, which sometimes became almost red hot. She did not appear to be in any way hysterical, and was anxious not to leave her post. She had noticed that the workers generally whose duties kept them on the opposite side of the building—away from the stoves—did not complain, although they did not seem so cheerful and talkative during the colder weather—when the stoves were burning—as at other times. Their employer was regarded as kind and considerate.

No examination of the blood was made, but the evidence seemed to point very clearly to a chronic poisoning by carbon monoxide produced by the passage of carbon dioxide gas through the red hot—or almost red hot—thin iron walls of the heating stoves. The patient was told that her symptoms were due to her propinquity to the particular kind of stove in use, and that I would write to her employer on the matter. This I did, stating my belief that, if the stoves now in use during the cold weather were replaced by a system of heating—as by hot-water piping, free from the serious risk to health involved by the method now in force—the necessary outlay would be more than repaid by the improved health and increased output of his employees. The reply to my letter was characteristic of the business thoroughness of my correspondent's American nationality. It told me that he had scrapped the present form of heating apparatus and had substituted for it hot-water pipes, flow and return, heated by a stove placed in a separate well-ventilated chamber which had no direct communication with the workroom. Three months later he wrote again to the effect that he was assured that he was receiving a handsome return on his outlay in the improved well-being and increased output of all his workpeople, to say nothing of a considerable reduction in the cost of fuel. The patient also informed me that she had lost all her previous discomfort since the new heating system had been installed. She certainly appeared to be in excellent health.

In the course of the same year I was consulted by a gentleman and his wife who occupied a large, modern, well-built house, in an open exposed situation in the country. Throughout the previous winter their general health and well-being—usually quite good—had steadily depreciated. Each morning they awoke feeling listless, depressed, and often with slight headache. These symptoms became less marked during the day, and by the evening they felt comparatively well. They were normally cheerful "open-air folk," but they now looked pallid, languid, and bereft of their usual energy. There appeared no very obvious cause for this change, and they denied having altered their usual habits and mode of life in any way—except that at the beginning of the cold weather an anthracite stove had been installed in their bedroom, and this had been kept burning ever since. They had still continued the custom of always sleeping with an open window. Further inquiry elicited the fact that the stove in question was constructed of ordinary cast-iron and was not enamelled. They were advised to replace it by a stove safeguarded by an external coating of good gas-proof enamel. This was done; the unpleasant symptoms disappeared, and the patients speedily recovered their good health. Three or four similar cases have come under my notice since, and I have heard of others. It seems probable that the mischief produced in this way may still be more common than one might have suspected.

Next in harmfulness to such carbon monoxide intoxication—although acting in quite a different way—is the too common expedient of heating a room by the use of a paraffin stove or lamp. This is often placed in the centre of the room, though occasionally on the hearth. But, unless placed actually within the chimney-throat, its effects are most pernicious, quickly robbing the air of a very large amount of oxygen, and at the same time fouling it with the products of combustion. Similarly, the condition of the air in the uppermost two or three feet of an ordinary room lighted by gas is intolerable—as will be obvious to anyone who mounts a pair of steps in order to rehang a picture under such conditions. It is seldom recognised how much of this vitiated air passes through the ordinary ceiling, which is merely a porous diaphragm, into the room above. If this be questioned, let the doubter pass a night in a bedroom so situated and compare his sensations during the night and on awaking the next morning with those which he experiences when sleeping in a bedroom situated above a room in which no gas has been burned during the evening.

### The Pressor-factor in Hyperpiesis.

The interest aroused in connexion with arterial tension—its maintenance within normal limits; the origin and causation of the various abnormalities which are so often present; and in particular, the explanation of the production of hyperpiesis *and of the several complications,* local and general, which are apt to attend its existence—has recently occupied a considerable amount of space in the medical journals and in the proceedings of medical societies. In this connexion, the details of the case described below should have, I believe, a value of their own, presenting a demonstration of what one may regard as hyperpiesis in its simplest form; the production of high arterial tension maintained for some years at approximately the same level, unattended by toxæmic or other complications, or apparent interference with health, produced and sustained by a merely functional stimulation of the adrenal bodies, due to a simple and unsuspected cause. It thus presents itself as a direct and uncomplicated example of cause and effect, affording to us, as it were, something like a standard, whereby we may recognise and disentangle—perhaps even measure—the various accretions, symptomatic and pathological, which are apt to confuse and puzzle us.

A married man of middle age, who had taken a large house in the country for the later summer months, had spent the greater part of the previous three years or more in undergoing various "cures" at numerous health resorts on the Continent and in England. During this time he had lost flesh considerably, though he was now by no means emaciated. While he could scarcely be described as a hyperchondriac, he had become very self-centred as regards his health and his diet and concerned as to the real nature of his illness, as to which he had received, according to his own account, a variety of rather conflicting diagnoses. Apart from his mentality, his condition revealed only one abnormal symptom; he slept fairly and peacefully; his appetite was small (he had continued to practise a limited dietary and his present weight had remained unaltered); he took a fair amount of light exercise with ease and enjoyment; the bowels acted well and regularly; his urine was passed in sufficient amount and was in all respects normal. There was no indication of cardiac hypertrophy. But he had an arterial tension of about 195 to 198 mm. (systolic), with a fair range. His pulse was regular and full, but not hard, and the walls of his arteries were so soft that, when the vessel was emptied of blood, it was impossible to be absolutely certain that they were detectable by the finger.

I wrote to his medical adviser in Town, asking, among other things, whether this symptom was normal to the patient, and, if so, for how long it had been noted. In reply I was told that for at least three years the blood pressure had been from 196 to often a little above 200 mm. Towards the end of the letter it was mentioned that about three years previously an X ray examination had revealed the existence of a small "latent" stone in each kidney. None of the several surgeons who had been consulted ventured to advise interference under such conditions, and, for obvious reasons, the presence of these calculi had not been made known to the patient.

Here seemed to lie the most probable explanation of the hyperpiesis. The kidneys and the adrenals have the same vascular and nervous supply, and it seemed reasonable to suppose that, while the encapsuled stones might as yet produce no definite renal symptoms, their presence as foreign bodies might, nevertheless, evoke a certain amount of continuous irritation of the compressed nerve-endings in the kidneys sufficient to bring about an increased nervous and vascular stimulation of the adrenals, and thus to initiate the hyperpiesis. One also recalled the fact that, in certain cases—e.g., an acute scarlatinal nephritis—the application of a large hot poultice to the lumbar region is followed by an appreciable softening of the previously hard pulse before any modification is noted in the amount or composition of the urine.

A large hot compress of Antiphlogistine was therefore ordered to be applied over the loins the same evening. When the patient was seen on the following afternoon the systolic blood pressure was found to be 130 mm. In other respects the patient's condition had undergone no alteration, except that he had slept rather better than usual during the previous night. During the ensuing four days the blood pressure gradually climbed up again to round about 100 mm.

The above clinical picture shows that increased activity of the adrenal bodies, if due to a simple non-toxic stimulation of their function, may continue for some three or four years at least without apparent effect on the patient's general health, and without producing any recognisable hypertrophy of the muscular walls of his arteries. It is not unlikely that if such adrenal stimulation were maintained for a prolonged period, some obvious thickening of the muscular coat would become perceptible: but this would be a natural and benign process—like the increase in the mass of his muscles during the training of an athlete. Moreover, in neither instance, should we expect any evidence of muscular degeneration so long as the exercise was continued, always provided that no toxic material were allowed to find its way into the circulation.

It is now generally admitted that, in a healthy individual, the regularly balanced action of the adrenals on the circulation is maintained by a correspondingly regulated action of the endocrine system. In the advanced—the down grade—period of life, the endocrine balance is apt to be distorted, often with a corresponding effect on the arterial tension; but even then it would appear that the arterial walls do not stiffen or degenerate if they be not subjected to some direct toxic influence brought to them by the blood they carry.

### CASCARILLA: AN UNDERVALUED DRUG.

In this country cascarilla is sometimes employed as a mild expectorant in bronchial affections. In Germany it is used—because of its tannic acid content—as an astringent in diarrhœa, and is regarded, "like many allied drugs, as a discarded remedy for fevers."[1]

Several years ago I learned that the Romany boy learns to smoke without passing through that unpleasant phase of discomfort and distress which is usually a vivid experience in the case of his Gorgio contemporary. This relief is secured to the gipsy boy by mixing with his tobacco a small amount of a certain brown powder—procured, at a price, from the wise women of his tribe. Of course, its use has to be combined with certain mystic rites and incantations, but the further consideration of these may be omitted, since they do not appear to be essential to success in the case of the heretic. The powder in question proved to be merely roughly comminuted cascarilla bark. These facts suggested that cascarilla affects not merely the pulmonary branch of the vagus nerve, but also its cardiac and gastric branches, and further observations proved this to be the case.

I will quote only one instance. In a comparatively recent epidemic of influenza, which was characterised by the sudden onset of acute gastro-intestinal symptoms, continuous painful and violent vomiting, general exhaustion, diarrhœa, irregularity and intermittence of a feeble pulse, and a very prolonged and tedious convalescence, the administration of cascarilla in aqueous infusion was attended by most satisfactory results. The mixture prescribed contained potass. citrat. or sod. bicarb., gr. xv., sp. æth. nitros. ♏ x. to ♏ xv., with equal parts of liq. ammon. acet., infus. cascarillæ and aq. menth. pip. or aq. chloroformi (according to taste) to ℥ i. Dose ʒ ss. to ℥ i. in water every two hours while awake, until the skin became decidedly moist, and then every three hours while awake. The only food allowed was water, hot and in frequent large doses, so long as vomiting continued; afterwards cold, with a small quantity of Bovril or of Oxo, for the first 24 hours. In only one of the 20 cases so treated was the vomiting so violent and exhausting that it had to be specifically checked by the administration of adrenalin (1 : 1000) ♏ vii. ss. in a wineglassful of water—a single dose of this proving sufficient. All were "quite comfortable," with normal pulse and temperature, by the end of 12 to 24 hours; at the end of the second day they expressed themselves as "quite well"—and seemed so—and gradual resumption of the ordinary diet was then begun, and they were allowed to get up after the seventh day. Convalescence in each case was speedy, uninterrupted, and complete. Other cases treated with the same mixture—except that the infus. cascarillæ was omitted—followed the prolonged and unsatisfactory course usual at the time.

In the case of patients convalescent from other debilitating conditions, who are still much "run down," without appetite, and often mentally depressed, a similar mixture, to which two or three minims of tr. nuc. vom. may be added, taken shortly before meals, often works wonders. It is, of course, important to make sure that a regular and sufficient action of the bowels is secured. It is equally serviceable when dealing with the various disabilities to which the heavy smoker is liable from time to time.

### IMMEDIATE MEDICATION.

This term is here used to signify the introduction of the medicament into the site of trouble instead of administering it by the mouth—only the beginning of a much more roundabout route. Perhaps the simplest illustration is afforded by the treatment of "lumbago" by the method recommended by Dujardin Beaumetz, so long ago that it is now almost forgotten: the subcutaneous injection of a few drops of an aqueous solution of sodium salicylate (1 in 40) into the site of pain.

I had run into a little harbour on the East Coast in order to get a leaking butt-end set right by the ship's doctor. Coming out of the hotel after dinner I spied an old friend and colleague standing under the veranda of the adjoining house. He was staying for a fortnight's golf, it seemed. The next morning, after breakfast, I found him sitting in the same place—in a chair packed with cushions—looking very unhappy. He was in the throes of a crippling lumbago; he told me it had taken him two hours to dress and golf was impossible. I asked what he was doing for his relief. "Nothing," he answered, "nothing does me any good; it must wear itself out." I suggested his injecting half a grain of sod. salicyl. dissolved in 20 minims of water into each loin. "Half a grain!" he rejoined, "why, I take it in doses of 20 and 80 grains and it has no effect." "But, by the time your 80 grains have run the gauntlet of your stomach, and have found their way into the 30 ounces of your circulation, how much of them reaches the seat of trouble?" He had not considered that. "Well," I said, "it is worth trying, and at once; by this time to-morrow it will not be very effective probably," and I went off to my boat. That same evening I found him sitting in the same chair—but without any cushions—smoking a big cigar and looking very pleased with himself. I asked after the lumbago. "Oh, that's all gone," he replied. "I did not believe a bit of what you told me, but I sent to the chemist's for a syringe and an ounce of the solution. I injected 20 drops into my right loin and in ten minutes the pain on that side had disappeared. So I injected another 20 drops into the other side, sent off for a cab, drove up to the links, and won my match." I have known many cases equally successful. So far, I have never known the treatment to fail if used within 12 hours of the commencement of the attack; in about 60 per cent. of such cases it is equally efficacious at the end of 24 hours. It never fails to give a certain amount of relief.

The following case is, in some respects, more dramatic. In the early hours of a winter morning I saw the stillborn child of a healthy primipara. Labour had been normal and not unduly prolonged. The cord was long, looped quite loosely round the child's neck. Flicking with a towel, hot affusions, artificial respiration, and tongue-traction had been persevered with for nearly two hours vainly. The child's body was stone cold, white, and its eyes were glazed and insensitive. The case looked quite hopeless. But one remembered that the infantile heart has some lacertilian qualities; and there was just a glimmer of hope, that if only one could once set the heart going, it might continue to do so. Compression of the heart by the hand would mean a mutilating operation. I was minded to try a simpler measure first. There was no ether at hand, but a really good brandy was obtainable. The child was rolled up loosely in a hot blanket, and laid on its back on the table over the edge of which its head depended. A hypodermic syringeful of brandy was then injected vertically into the centre of the cardiac dullness to the left of the sternum. Tongue-traction was then resumed. At the third pull there was a slight gasp; this was repeated, more strongly at the fifth pull; and thereafter chest compression was gently used to reinforce expiration. In five minutes the skin had become pink and the child began to wail. The mother, who had fortunately been sleeping, then awoke. The child was dressed and given to her, and took the breast readily. It never looked back, and three years later I was shown his photograph—as bonny, plump, and well-developed a youngster as one could wish to see.

## YEAR BOOK OF UNIVERSITIES OF THE EMPIRE.

THE 1926 edition of this useful year book has been edited, as before, by Mr. W. H. Dawson, and is published for the Universities Bureau of the British Empire by Messrs. G. Bell and Sons, price 7s. 6d. The year book, which was first published in 1914, has no light task to fulfil, for the calendars of the 67 British universities form in themselves a library of imposing dimensions, some 50,000 pages, and are hardly accessible in their entirety anywhere than at the Bureau. The year book makes the attempt to extract from each of these bulky volumes such information as is likely to interest members of other universities and colleges, Government departments, school-masters, and the public generally. Medicine is largely represented in the year book, the section, for instance, which deals with the medical schools of the University of London (pp. 154 to 167) giving useful general information regarding the large teaching schools and the other institutions at which medical instruction is available in London. Appendix 26—which can be obtained in pamphlet form from the Bureau free of charge—supplies a list of professional schools, specialist studies and post-graduation courses, indicating to what extent each university undertakes work which is not common to all. Appendix 25 contains brief notes of the principal universities in the United States, those on foreign universities given in previous editions having been discontinued in view of the publication by the National Union of Scottish Students of a new Handbook on Foreign Study. The year book contains an index of names and an index of colleges and institutes, as well as a general index. It is conspicuous throughout for its accuracy and ease of reference. The address of the Universities Bureau is No. 50, Russell-square, London, W.C. 1.

## INDUSTRIAL WELFARE WORK.

A RECENT publication by the firm of Reckitt and Sons, Ltd., describing the welfare work carried out in their factories and workshops, gives a good idea of how some of the general principles of industrial welfare may be applied to a specific industry. There can be few firms which have such a long and successful history of this kind of effort. The first lady welfare worker was appointed in 1906, and in the following year a works council was instituted. This was a far-sighted and wise move, and the development of welfare work on a coöperative and democratic basis has resulted in a fine organisation. This is mostly under the management of the employees themselves with the technical assistance of the welfare workers who now play an integral part in the firm's activities. In Hull the firm employs a full-time doctor, whose duty it is to look after the general health of the workers and to examine applicants for employment, and a full-time dentist examines the teeth of all applicants and gives the necessary dental treatment. A nurse is on duty during factory hours and a visitor goes to see any employees who are confined to their homes. The various clubs, educational institutions, and sports organisations also occupy a large part of the welfare workers' activities.

## COUNTER-ATTRACTIONS FOR THE SAILOR.

A COMMITTEE of the United States Navy has been considering the prevention of venereal disease; the committee was exceptional, for there served on it no officer above the rank of commander—a committee, therefore, of junior officers only, and on that account, if for no other, memorable. Venereal diseases, they say, cause much loss of service, but how much is not accurately known. To make registration as complete as possible they recommend that no man shall lose pay or leave because of these diseases. As to their origin, it is observed that they are always contracted outside the service, and that the self-indulgence that makes them possible is learned not in the Navy but in childhood. Men naturally seek the society of women, and of good women if they are attainable. But it is less easy to become acquainted with these good women, so the committee recommends (*U.S. Naval Medical Bulletin*, December, 1925) that the Admiralty shall employ "at whatever salary necessary" a woman of agreeable and forceful personality, a trained social worker, to organise a corps of clever women willing to initiate social functions for the sailors in the ports and so to keep them out of mischief. If the Bureau of Navigation accepts the recommendation it will be interesting to see the results.

## THE VENTILATION OF KITCHENS.

THE relation of the various methods of producing heat in dwelling-houses to health and disease is a subject on which laymen and, indeed, doctors often hold strong, if not prejudiced, views. The argument set forth by Dr. Vernor Sinclair in a small treatise[1] recently published is that carbonic acid, carbon monoxide, sulphurous acid, and ammonia arising from gas cooking stoves and closed combustion stoves are responsible for a number of illnesses including nasal catarrh, acid dyspepsia, rheumatoid arthritis, asthmatical conditions, diabetes, cancer, and various nervous states—e.g., neurasthenia. The evidence put forward in support of this argument is scanty and by no means convincing. There is at present no evidence, either statistical or experimental, that such gases, under ordinary conditions, ever accumulate in sufficient quantities to cause poisoning. Moreover, Dr. Sinclair admits that men are more frequently affected than women, although women spend far more of their time in proximity to such cookers and heaters. He gets over this difficulty by stating that man is less resistant to disease than women. In a foreword he states that plants in conservatories and greenhouses would die if gas and coke combustion products were allowed to enter these buildings; therefore, the heating apparatus is placed outside, and he argues that the same should hold for rooms for man. We know of some greenhouses where the heating apparatus is inside. It is possible to have sufficient air-flow to carry away combustion products if the heaters are inside hothouses, but the expense is greater. In ordinary rooms designed for human occupation, including kitchens, there is sufficient ventilation to carry away the products of combustion, so that there would appear to be no need to find other situations than those at present in use for cookers and heaters if the ventilation is efficiently controlled.

## "OLD AGE MUST COME . . . ."

*To the Editor of* THE LANCET.

SIR,—I have read with much interest the note under this caption in your issue of Jan. 30th (p. 268) in which you state that "the idea of an extra ten years of enforced idleness after a busy and interesting life does not appeal to everyone," and imply that there may be some good fortune in being carried off by pneumonia in early old age.

The question you raise is an exceedingly important one in its bearing upon activities in public health and personal hygiene. The apathy or cynicism, if you please, of many people towards a programme for increasing the vitality and longevity of the race is a serious hindrance to the adoption of such measures as the periodic health examination and the acceptance of the counsel based upon the results of such an examination. Hence I am prompted to ask space for a presentation of the true thesis that underlies the movement for the extension of human life.

When the statement is made that ten years may be added to human life, it is natural for many people to picture individuals ranging from 65 to 75 years of age having ten years added to an existence that, on the average, is none too comfortable or satisfying. This, however, is not a true picture of the situation when ten years have been added to the average lifetime. In the United States about a dozen years have been added to the average lifetime in the past 37 years, but this certainly has not been accomplished by prolonging the lives of people over 60. It has been accomplished chiefly by a reduction in the death-rate under age 5. There has been little extension of life beyond the age of 50.

It is true that the present objective of the life extension campaign in this country is toward a reduction of the death-rate in later life, especially through the medium of periodic health examinations. The combined efforts of health workers in the various fields may be counted upon to reduce the death-rate at every age-period of life. And, most important, the reduction in the death-rate beyond age 50 and the carrying forward of the ultimate span of life to a much later period will be accomplished only through improving the vitality during the so-called active periods of life, and, in fact, materially prolonging that active period. It may be possible that the actual period of what we now picture as old age will be shortened.

In my judgment, the most pitiable aspect of the present situation of civilised man is the comparatively brief period of youth—what I have termed the health span—which actually persists, on the average, not more than ten years. This period of exuberant youth when the individual is in possession of the full ample reserves of power should be greatly extended. The work span—that is the period during which working men are regarded as so-called good risks—does not extend much beyond 45. The object of the life extension movement is to extend this period beyond 60. These are the constructive, attractive, and actual ends in view rather than adding a few feeble years to an already feeble existence.

As I have elsewhere expressed it, there is no purpose in the life extension movement to merely hang on to the coat-tails of Father Time, but rather to start as early in life as possible to equip the individual for a long and successful period of living, interpreting success as satisfaction in living in the highest sense of the term.

I may say, incidentally, that in the course of this work I meet a very large number of elderly people who are very eager to have their lives extended. The complacency with which men who have not yet felt the touch of old age state that they will be very glad to have their period of old age shortened, is rather rarely found among those who have actually reached that critical time. The will to live, or rather the desire to live, is a very widespread, in fact universal, characteristic of old age.

I am, Sir, yours faithfully,

EUGENE L. FISK, M.D.,
Medical Director, Life Extension Institute,
Inc., New York.

March 28th, 1926.

# Hunterian Lecture

ON

# NEOPLASMS OF THE TESTICLE.*

*Delivered before the Royal College of Surgeons of England on Feb. 12th, 1926,*

By H. W. B. CAIRNS, M.B. Adel., F.R.C.S. Eng.,
HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS;
*ASSISTANT SURGEON TO THE LONDON HOSPITAL.*

THE great majority of testicular tumours fall into two main groups: (1) *Mixed tumours.* This term is here used in its widest sense to denote tumours composed of several types of tissue, all of them truly neoplastic. (2) *Spheroidal-celled tumours*, which, according to the interpretation of individual workers, have been variously described as alveolar sarcoma, carcinoma, séminome, spermatocytoma. Having studied at the London Hospital some 95 tumours of the testicle and its adnexa, I have found that 93 per cent. of the primary tumours of the testicle itself belong to one or other of the above groups. The two groups are approximately equal in their frequency.

Thanks largely to the classic paper of Wilms[1] in 1899 it is now generally realised that the mixed tumours are teratomata. Numerous views have been advanced as to the nature of the spheroidal-celled tumour, but it is only necessary here to mention the view of Ewing,[2] who claimed in 1911 that spheroidal-celled tumours were teratomatous. More recent workers have declared against this view, but, from the evidence provided by this series of cases, I believe that Ewing was right in his main contention, and that these common tumours are one and all teratomatous.

## General Consideration of Teratomata.

At the outset it is very necessary that I should place before you the views at present held as to the nature and origin of teratomata. I need scarcely point out that there is no measure of finality in these views, for the simple reason that the subject in its essence is intimately connected with, and dependent upon, some of the unsolved though fundamental problems of human biology and embryology. All that we seek is the best explanation of the facts about teratomata so far as they are known.

It is generally agreed that a mixed tumour which contains derivatives of all three germinal layers (epiblast, mesoblast, and hypoblast) is a teratoma. If the tissues of the tumour are of the fully differentiated adult type, and if their arrangement is more or less orderly and imitative of structures in the adult body, then the teratoma is said to be typical or adult. If, on the other hand, the tissues are in a state of incomplete differentiation and are wanting in orderly arrangement, then the teratoma is atypical or embryonal. In reality, there is no sharp morphological line of division between these two groups, yet the terms have a definite value clinically, and they also make us recognise a remarkable quality exhibited to a greater or lesser degree by every teratoma—the quality of differentiation.

The teratoma must be conceived to represent a separate individual, "an autonomous growth, the product of the continued development within one individual of another individual of the same species" (Adami[3]). There are many observations, both macroscopic and microscopic, which support this conception, but the actual proof rests upon the discovery of chorionic elements in teratomata. In 1902 Schlagenhaufer[4] demonstrated areas of chorion carcinoma in teratomata of the testicle, and his observation has since been amply confirmed. Chorionic elements are undeniably fœtal, and their presence in teratomata, therefore, proves conclusively that such tumours are to be regarded as separate individuals. The stimulation of the breasts to secretory activity by these tumours, a point referred to below, is further evidence of their fœtal nature.

As Adami has pointed out, teratomata are best explained as arising from totipotent cells—that is to say, cells which possess the power of giving rise to every order of cell in the body. First and foremost among such cells is the fertilised ovum; but there are also other totipotent cells, chief of which are the germ cells, and the first products of somatic development, the primordial blastomeres. As somatic development proceeds the cells of the body become more and more differentiated, and at the same time more and more restricted in their potentialities. Whereas the primordial blastomeres are totipotent and are capable of giving rise to an individual, the cells of the three-layered embryo are at first pluripotent but ultimately become unipotent; when the fœtus is fully differentiated the cells of any organ or tissue only give rise to like cells.

If we accept this view it is no longer possible to regard teratomata as arising from the paradidymis, or, as some recent writers[5] have it, "possibly from some vestigial mesonephric structure." The mesonephros is mesoblastic, and cannot give rise to the epiblastic or hypoblastic components of a teratoma. There is at present no evidence in favour of the view that metaplasia can occur between tissues of different germinal layers.

In the testicle, as in other organs in which teratomata of tridermal (triphyllic) structure occur, there are also found mixed tumours in which it is only possible to demonstrate derivatives of two germinal layers (diphyllic tumours). These are best regarded as being truly teratomatous and arising from totipotent cells. For, apart from the fact that absence of derivatives of one germinal layer may be merely apparent and due to incomplete microscopic examination, there is no reason to suppose that a totipotent cell must always exert its full potentiality. For similar reasons tumours of the testicle which contain multiple derivatives of one germinal layer (monophyllic mixed tumours) may be regarded as teratomatous. Here, however, my experience leads me to the conclusion that a thorough examination of mixed tumours of the testicle never fails to reveal evidence of structures derived from at least two of the germinal layers.

## Teratoma Testis.

### 1. *Typical Teratoma (Testicular "Dermoid").*

*Structure.*—This tumour bears a very close resemblance to the more common "dermoid cyst" of the ovary. It consists usually of a large cyst, lined by skin and filled with hairs and sebaceous material. When the main contents of the cyst are cleared away there is found on some part of the cyst wall a protuberance (embryonal rudiment, or Zotte), which contains many diverse structures—brain tissue, teeth, bone, cavities resembling œsophagus and trachea, and so forth. In testicular "dermoids" the embryonal rudiment may sometimes be very large and may almost completely fill the cavity of the main cyst, thus giving to the tumour a more solid appearance. Occasionally the main cyst is lined by nervous tissue, as in a beautiful specimen taken from a cryptorchid colt, and kindly placed at my disposal by Mr. Frederick Hobday. A thorough histological examination of these tumours never fails to reveal evidence of their triphyllic structure.

*Habits.*—The testicular "dermoid" is common in the horse, and is in that animal frequently associated with cryptorchidism (Hobday[6]). In man it is a rare tumour, and I have only been able to find records of 47 undoubted cases. From an analysis of t
it is possible to confirm the contention of
that the tumour is congenital, for of the
data were available 92 per cent. were
or shortly after birth, and in 84 per c

* The work on which this lecture is based will be published elsewhere at a later date.

appeared within the first year of life. In only 5 out of 44 cases was the tumour first observed in adult life, and in one of these (Lexer [8]) the testicle lay within the abdominal cavity.

The tumour runs a remarkably benign course. It may exist for as long as 40 years before the patient seeks relief. I can find in the literature no authentic record of spread by metastases, nor can I find any histological study which provides undoubted evidence of malignancy of the testicular "dermoids." Similar tumours in other parts of the body occasionally become malignant, so it is not impossible that testicular "dermoids" may do the same. For the present, however, we may conclude that the tumour is essentially benign.

*Site of Origin.*—The occasional appearance of an almost normal testicle at one or other margin of the tumour suggests the idea, first advanced by Verneuil, that the "dermoid" has an extra-testicular origin. There are, however, now on record a number of cases in which the "dermoid" is entirely surrounded by testicular tissue, and the published cases on critical examination furnish no proof that the growth arises outside the testicle. Verneuil conceived the testicular "dermoid" to be the inclusion of a parasitic fœtus. This we now know to be incorrect, for "dermoids" arise in undescended testicles, where, according to embryologists, fœtal inclusion can never occur.

### 2. *Atypical Teratoma (Mixed Tumour).*

The atypical teratomata occur with much greater frequency than do those of the preceding group, for they comprise approximately half of all the primary tumours of the testicle. In design they follow the same general lines as the typical teratomata, but they differ remarkably from the latter in their extreme malignancy. They are found most commonly in adult life between the ages of 20 and 40 years.

*Structure.*—These tumours are composed of many different tissues in various stages of differentiation. They present in complex array tissues similar to those found in the normal fœtus—cartilage, involuntary muscle, jelly tissue (the so-called "myxomatous" tissue), tubules or cysts lined with columnar epithelium usually of a mucous type, stratified squamous epithelium, and so forth. But they contain also other tissues, so little differentiated that it is impossible to determine what part of the organism or which germinal layer they represent. These "undifferentiated" tissues usually predominate.

The tissues found vary widely in individual tumours, and the naked-eye appearances are correspondingly variable. The most usual type is a solid tumour composed of soft, white, necrotic and hæmorrhagic tissue with here and there a few cysts, or tiny lobules of cartilage. In such tumours a most thorough examination is necessary to obtain evidence of a triphyllic or even a diphyllic structure. A more unusual type of tumour is one which, composed largely of differentiated tissues, presents to the naked eye a "fibro-cystic" appearance, or a preponderance of cartilage. The one characteristic macroscopic feature of atypical teratomata is that the living portions of the tumour are not perfectly uniform in appearance.

The quality of differentiation is remarkably well shown by these tumours. Their tissues differentiate in the same way as do those of the normal fœtus. All transitions can be observed between the earliest cartilage, appearing in the centre of a group of spindle cells, and cartilage which is undergoing ossification. Primitive voluntary muscle-fibres are seen to assume transverse striation of their cytoplasm. Tubules lined with mucous goblet cells become surrounded by first a circular, then an outer, longitudinal coat of involuntary muscle; they are forming by their differentiation a perfect imitation of primitive gut. Megaloblasts are seen losing their nuclei, becoming thus transformed into erythrocytes. . . .

The observation of these differentiations provides a most fascinating but time-consuming histological exercise. The changes can usually be followed only in those structures which, like cartilage, present a distinctive and easily-recognised histological picture. But anyone thoroughly familiar with the histology of the early embryo could doubtless trace similar changes in other structures of the tumour, particularly in the structures of glandular type.

*Malignancy.*—A certain hesitancy is evident in many of the writings on this question. Earlier workers were inclined to regard the atypical teratomata as benign, but liable to undergo malignant change. Concerned mainly with establishing the fact that fibro-cystic and certain of the solid tumours of the testicle were actually teratomata, they neglected to follow up their cases. They were influenced in their views by the behaviour of the typical teratomata or "dermoids," already shown by Verneuil to be benign, and doubtless also by the observation that atypical teratomata may exhibit remarkable variation in their rate of growth. But this peculiarity is shown also by the metastases of atypical teratoma. Both primary and secondary tumours may remain apparently stationary for years without affecting the health of the host. Then suddenly, perhaps after an injury, they take on rapid growth, and by further extension soon destroy their host. I was able to observe a remarkable case in which a metastatic lump in the groin, appearing soon after removal of the primary tumour, remained almost stationary for over two and a half years, and only began to grow rapidly after it had been examined by a large class of students. Post hoc or propter hoc? I do not know. But whatever its cause this rapid growth of the lump was associated with further extension of the disease, and the man was dead within six months.

On following the life-history of a number of cases it is evident that the atypical teratomata of the testis are among the most malignant tumours known to man.

The after-history of 34 of the 35 cases of this series, which was begun in 1908, has been traced to the end of 1925; 22 have died of metastases, in 12 cases within six months of the onset of symptoms. On histological examination the tumour is seen to spread by invasion of the surrounding testicular tissue, the epididymis, spermatic vessels, tunica vaginalis, and even the scrotum. With histological evidence of this nature it has been possible to show that 80 per cent. of the cases of this series were malignant.

The metastases usually have a mixed structure. In six of the ten cases of this series in which metastases were examined, derivatives of two germinal layers were found, and in one other case they contained derivatives of all three layers. While they are composed chiefly of undifferentiated tissue, the metastases occasionally show structures of a perfectly benign appearance; for example, tubules lined with a single regular row of mucous goblet cells and surrounded by a layer of involuntary muscle. It sometimes happens that the metastases consist almost entirely of a differentiated tissue of benign appearance, as in Paget's famous case,[9] where the lungs, inferior vena cava, and spermatic vessels were occupied by cartilage. In other cases the differentiation of certain elements may be more advanced in the metastases than in the primary tumour. Occasionally the metastases present tissues not found in the primary tumour.

It is only by regarding the atypical teratomata as inherently malignant that these varying appearances can be explained. The primary tumour contains cells of differing potentialities. Any or all of these cells can spread to distant parts and there produce metastases. And in spreading they do not lose their power of differentiating. They are still capable of producing in the metastases perfect imitations of parts of the fœtus, structures of histologically benign appearance. It is, therefore, clear that the teratoma is not malignant through having undergone a "sarcomatous" or "carcinomatous degeneration," as some writers would have it. The tumour is inherently malignant. Both primary and secondary tumours are teratomatous.

### 3. *Chorion Carcinoma.*

Chorion carcinoma is found within the testicle either alone or in association with mixed or other teratomatous tumours of the testicle. *Its structure is identical* with that found in chorion carcinoma in women. It is extremely malignant. The primary tumour is occasionally small, and thus it happens that the patient frequently presents himself for symptoms produced by the metastases.

In a case, the details and materials of which were kindly placed at my disposal by Mr. Foster, of Reading, a man of 23 came complaining of a swelling of the left side of the face and a discharge of blood from the mouth. The left superior maxilla, which contained growth, was excised, and histological examination showed chorion carcinoma. Further examination then showed that the left testicle was the size *of a small tangerine orange, hard and devoid of testicular* sensation. The man died of extensive metastases five weeks after the appearance of the swelling in the face. The testicle contained a chorion carcinoma.

### 4. *Spheroidal-celled Tumour (Séminome).*

*Structure.*—This tumour is composed of a perfectly *homogeneous* white or greyish-white tissue, which is divided into lobules by fine and coarse fibrous strands. Areas of necrosis are almost constant, and small points of hæmorrhage frequent. The tumour is usually large, but a small scirrhous type also occurs, in which the fibrous septa are broad and the lobules of growth correspondingly diminished in size.

Microscopic examination reveals no mixture of tissues, but a tumour entirely composed of large spheroidal cells of striking appearance. Perhaps the most characteristic features of these cells are the prominence of their nucleoli, the powdered appearance of the nucleus, and the abundance and vacuolation of their cytoplasm. Multinucleate forms occur. The cells are arranged in large solid acini and trabeculæ. Within the acini, as Prof. Turnbull has long pointed out in his lectures, the formation of tubules is not infrequently seen. The tumour is extensively infiltrated with small round cells, chiefly small lymphocytes, but also plasma cells and eosinophile leucocytes.

*Habits.*—The spheroidal-celled tumour is undoubtedly malignant. Metastases were found in 21 of the 41 cases of this series. In the remaining 20 cases evidence of spread by invasion was obtained in all but three cases. The tumour is essentially one of adult life, and on the whole it tends to appear at a later period than does the atypical teratoma.

### 5. *"Combined" Types of Teratoma Testis.*

Recognition of the teratomatous nature of the spheroidal-celled tumour of the testis was due *primarily to the discovery of tumours which, to the* naked eye, were partly spheroidal-celled tumours and partly atypical teratomata. Observations of this nature were first made by Lecène,[10] and have since been confirmed by Ewing,[3] Jeanbrau and Massabuau,[11] Ferrero,[12] and others. In the London Hospital series of 77 cases there were six tumours in which the association of spheroidal-celled tumour with atypical teratoma could be recognised macroscopically. And in one of these there was, in addition, a large area of chorion carcinoma.

MR. MILNE'S *Case.*—This was a man aged 28, who died of metastases three months after swelling of the testicle was first observed. The testicle measured 9 × 7 × 5·5 cm. It was chiefly occupied by chorion carcinoma, but contained also hyaline cartilage, stratified squamous epithelium, and tubules lined with a single regular layer of columnar epithelium. In addition, on the posterior aspect of the upper pole there was an almond-shaped area (3·5 × 1·1 cm.) of homogeneous white tissue, which on microscopic examination proved to be typical spheroidal-celled tissue.

But the *microscopic evidence* is much more abundant. Atypical teratomata almost invariably contain among their undifferentiated tissues large irregular tubules and ill-defined solid acini, composed of cells which are identical in their structure with the cells of the spheroidal-celled tumour. Such cells were found in 32 of the 35 atypical teratomata of the present series. This point has been noted by Ewing.

## THE ORIGIN OF TERATOMA TESTIS AND ALLIED TUMOURS.

As far as I am aware no direct observation has *yet been made upon the origin of teratomata*, either within the testis or elsewhere. The teratomata of the testicle are best explained as arising from totipotent cells. Of these there exist many in the normal testicle, and it is therefore not necessary to suppose, nor is it even probable, that the tumours arise from other totipotent cells, such as "dislocated" primordial blastomeres or primordial ova persisting within the testicle.

Work on the origin of the spheroidal-celled tumours throws suggestive light on the genesis of the whole group of teratomatous tumours. From the time of *Langhans*[13] *many observers of note have maintained* that they can trace the origin of the spheroidal-celled tumour from the seminiferous tubules. In support of this claim Dew[14] has recently brought forward some important observations. Ewing, recognising that the spheroidal-celled tumour is undoubtedly teratomatous, has gone yet further and has interpreted the tumour as representing the overgrowth of one element of a pre-existing teratoma. He regards the spheroidal-celled tumour as a teratogenous blastoma and rejects the claim that it arises from the seminiferous tubules.

There have thus sprung up *two apparently irreconcilable* schools of thought: the one holds that the spheroidal celled tumour arises in the seminiferous tubules, the other claims that the tumour arises in a teratoma. My own observations show that *the* spheroidal-celled tumour is teratomatous in nature, but they do not provide evidence from which we may conclude that the tumour actually *arises* within a teratoma. In atypical teratomata transitions from spheroidal cells to mucous goblet cells and to squamous epithelium are clearly demonstrated; transition to mesoblastic tissue is not definite. The relations of the cells thus suggest that they may be differentiated to the extent that they are hypoblastic, but it is only possible to say that they are poorly differentiated cells, and that no less differentiated cell can be recognised in teratomata. They may, indeed, be the primary, totipotent cells of teratomata, and I have found some evidence that they do arise within seminiferous tubules.

Further work may, therefore, reconcile the two conflicting views, showing that the spheroidal cell arises within seminiferous tubules and that it is a totipotent teratomatous cell. Such an explanation as this would be in perfect accord with our knowledge of the seminiferous tubules. For, as Prof. Turnbull has pointed out to me, spermatogonia are totipotent cells which possess the power of dividing into cells of similar potentiality. A tumour arising, for instance, from spermatogonia would be *a multiplication of cells* which apparently have all the potentiality of totipotent cells; any or all of them could form a teratoma. This view would explain well the varieties of tumour which are found in the teratoma group, and would provide for their common origin. (1) Tumours composed entirely of undifferentiated (totipotent) cells = spheroidal-celled tumours. (2) Tumours composed of tissues in various stages of differentiation = teratomata. (3) Tumours composed of a mixture of undifferentiated (totipotent) cells and differentiating tissues = the "combined" tumours.

## INTERNAL SECRETION AND TERATOMA TESTIS.

It is a remarkable fact that true hypertrophy of the breasts may follow the development of teratoma *testis or of its metastases*. The phenomenon was observed in two cases of this series. The enlargement in both cases coincided with the development of the metastases. In one case, under the care of Sir Hugh Rigby, the breasts were examined at necropsy. They measured 8 cm. in diameter and up to 1·7 cm. in depth, and they contained very numerous dilated ducts and ductules, which showed proliferation and desquamation of their lining epithelium. In another case of this series the patient gave a history of transitory swelling of the breasts and axillary glands, two months before the swelling of the testicle was first observed. Three cases of this type are reported in the literature by Garbarini,[15] Cooke,[16] and Warthin,[17] and my friend, Dr. Archibald Malloch, of Montreal, informs me that he has had one case. In Garbarini's case the breasts subsided after removal of the affected testicle. In the cases of Cooke and Warthin and Malloch the testicle contained chorion carcinoma.

These observations provide indirect evidence in support of Starling's original contention[18] that the normal fœtus produces a hormone which acts *directly* upon the breasts. Sacchi[19] has reported an interesting case in which a tumour of the testicle was associated with male sexual precocity.

### ÆTIOLOGY OF TERATOMA TESTIS.

*Relation to Injury.*—It is unlikely that an injury of the testicle can by itself give rise to a tumour. For, whereas tumours of the testicle are uncommon, almost every active male receives at some time or other in his life a blow on the testicle. Yet there is a definite association between injury and testicular tumour. In 14 of the 79 cases of this series in which the clinical history was recorded the testicular enlargement followed, or was first observed, shortly after a local injury. Other observers have obtained a history of injury in as many as 50 per cent. of their cases.

Writing in the eighteenth century Percival Pott[20] recognises that cancer follows injury of the testicle; he continues, "but (to say) that previous to such accident, there was no cancerous disposition or malignity in the habit, is an inference that cannot be admitted." The following remarkable case suggests that the true relationship between injury and tumour of the testicle is expressed in this cautious proviso of Pott's.

MR. WALTON'S *Case.*—S. B., aged 40, had been wounded by a bomb in February, 1918. From a recent examination of the scars it appears that a projectile had seared a transverse groove across the front of the upper part of the left thigh, and had then passed through the lower part of the scrotum and the hamstrings of the right thigh. Four months after being wounded the patient noticed that the left testicle was enlarged. From that time it gradually increased in size until his admission to hospital in July, 1919.

The left testicle was enlarged and hard. In the right side of the scrotum there was a small isolated nodule about 1 inch in diameter. This nodule lay in the subcutaneous tissue alongside of one of the scars. It was not attached to the right testicle, which was normal. At operation Mr. Walton removed the left testicle and spermatic cord, and at the same time excised the nodule and overlying skin from the right scrotum. The left testicle was entirely occupied by a typical spheroidal-celled tumour, save at the lower pole, where there was a small cyst (3·5 cm. diameter) immediately beneath the tunica albuginea. The nodule from the right scrotum had a microscopic structure identical with that of the primary tumour.

When last seen, over six years after operation, the patient was perfectly well and showed no signs of further metastases.

Bearing in mind that the scrotal metastasis was evidently solitary, and that it occurred in a most unusual position, in the track of a projectile, I suggest that the most adequate explanation of this case is to suppose that the testicular tumour was already present before the patient was wounded, and that the metastasis was produced by the carriage or spread of tumour cells along the path of the projectile. There is, therefore, reason to suspect that injury of the testicle does not give rise to the neoplastic process; its part is rather to stimulate to more rapid growth a pre-existing but hitherto unobserved tumour.

*Relation to Undescended Testis.*—While in the horse teratoma testis is commonly associated with cryptorchidism, in man there is no such close relationship. Mr. Russell Howard,[21] from a wide experience, concludes that there is no great difference between the relative frequency of malignant disease in the imperfectly descended testis and in the normal organ. In only five of the 77 human cases of this series was the affected testicle not in the scrotum. In three cases it was in the iliac fossa, and in two others it was lying on the external oblique. In one of these two torsion of the spermatic cord had occurred; the tumour (2 cm. in diameter) was only discovered after removal of the testicle. There were two other cases in this series in which a scrotal testicle contained a tumour, while the other and undescended testicle was unaffected.

### THE EXTENSION OF TERATOMA TESTIS.

With the single exception of the typical teratoma or "dermoid" all varieties of teratoma testis have been shown to be extremely malignant. There are minor variations in the intensity of the malignancy: chorion carcinoma destroys the host with astonishing speed, and the atypical teratoma is more rapidly fatal than is the spheroidal-celled tumour. It is, perhaps, for this reason that invasion of the epididymis is most frequently seen in the spheroidal-celled tumour.

In all varieties of teratoma testis, metastatic extension occurs by way of the veins or lymphatics of the spermatic cord, and results usually in the development of a secondary tumour in the lumbar glands. In 29 out of 33 cases in which data were available the first metastases to appear were situated either in the lumbar glands or along the course of the spermatic vessels. We may conclude, therefore, that the operation designed for the removal of the spermatic vessels and lumbar glands does at least rest on a sound basis of morbid anatomy.

In the lumbar glands the metastases usually grow to an enormous size and eventually form a huge confluent mass, through the centre of which pass the abdominal aorta and inferior vena cava. The mass is palpable above and not below the umbilicus as a deeply-placed ill-defined swelling. Its clinical importance is not confined to the fact that it provides evidence of the inoperability of any particular case, for by its invasion of surrounding structures it produces diverse clinical pictures, the significance of which may elude the observer if the primary tumour has escaped notice. The lumbar mass may invade the lumbar vertebræ and produce paraplegia, as in a case quoted by Curling.[22] Both ureters may be obstructed with resulting hydronephrosis and uræmia. Destruction of the adrenal bodies doubtless accounts for the extreme wasting which occurs in many cases. But the most common clinical manifestation of the lumbar metastases is, undoubtedly, intestinal obstruction, due to the formation of adhesions between small intestine and the anterior surface of the growth. Invasion of the lumen of the inferior vena cava is also a frequent occurrence; it may be followed by thrombosis of the vein and great œdema of the legs, or by a pulmonary embolism. Perhaps the most remarkable case in this series, from the clinical point of view, was one in which a neoplastic embolus passed from the spermatic vessels to the heart, thence by way of a patent foramen ovale to the right middle cerebral artery. This patient was at work when he suddenly had a "stroke." He died a few days later.

### THE OTHER TUMOURS OF THE TESTICLE.

Now that so many tumours are recognised to belong to the teratoma group, the question arises whether there really are any other primary tumours of the testicle. There occur in this series three cases which must from their structure be regarded as fibromyosarcoma, round and spindle-celled sarcoma, and angeio-endothelioma respectively. Such tumours could certainly arise from the stroma of the testicle, but it is difficult to be sure that they are not teratomata, for in each case the microscopic examination was limited to a small portion of the tumour.

*Lymphosarcoma.*—There is, however, one distinct and homogeneous tumour which, so far at least, has not been proved to be teratomatous—that is the lymphosarcoma. I have encountered three such cases. The tumour is entirely composed of small cells which measure 5 to 9 microns in diameter. The cytoplasm is relatively scanty, the nucleus notched or lobed, and deeply stained. The cells infiltrate the stroma of the testicle without destroying the seminiferous tubules. They themselves form no connective tissue. A very characteristic picture is thus produced. Microscopically the seminiferous tubules appear as islands amid a sea of tumour cells, and on naked-eye examination the tumour, which is of rubbery consistence, still faintly reveals the pattern of the normal testicle. It has, too, something of the colour of the normal testicle. The tumour is extremely malignant; metastases rapidly appear in many tissues and organs, particularly in lymphatic glands.

It is impossible at present to state the exact nature of these "lymphosarcomata." Their cells possibly arise from blood-forming cells and may be teratogenous.

### CLINICAL DIAGNOSIS.

Early diagnosis is important. Mr. Hugh Lett removed a testicle which contained near the hilum a spheroidal-celled tumour only 2 cm. in diameter. The veins of the lower part of the spermatic cord were nearly all filled by growth. But in spite of this the patient was alive and well when last heard of, 12 years after the operation. There are no specially distinctive features about the swelling produced by tumour of the testicle, and the condition is frequently confused with hæmatocele, gumma, and tuberculous epididymitis. Palpable lumbar glands are, of course, diagnostic, but the diagnosis should be made before the appearance of the metastases if it is to be of any practical value. To appreciate the finer points of a scrotal swelling it is best always to examine the patient in the recumbent position.

*Hæmatocele.*—When a hæmatocele is large and its blood content still for the most part fluid, it may be distinguished from a large testicular tumour by the fact that its surface is uniformly smooth, whereas in tumour small nodular projections can almost always be felt on some part of the surface. French diagnosticians lay stress on the fact that the head of the epididymis is not palpable in hæmatocele, but as it is always invaded by growth, or greatly compressed, in large tumours of the testicle, this point is of little value practically. It is almost impossible to distinguish between the old solid and calcified hæmatocele and a tumour, but the treatment is the same for both.

*Gumma.*—It is scarcely an exaggeration to say that the Wassermann reaction should never be employed in the differential diagnosis of gumma and neoplasm of the testicle. A positive Wassermann reaction indicates the presence of a syphilitic lesion, but that lesion may not be the one under surgical observation. In three cases of this series the discovery of a positive Wassermann reaction resulted in a long and unnecessary delay of operative treatment, while the patient received injections of novarsenobillon. A simple and effective method of distinguishing the gumma is provided by the oral administration of mercury and iodides. The effect of this mixture upon a gumma is most dramatic: often within three days the testicle begins to shrink. It is safe to say that if within a week there is no change in its size, then the swelling is not a gumma. This method should be used in all doubtful swellings, for the delay of operation is negligible. In my experience the mixture of mercury and iodides has no effect upon the size of tumours.

*Tuberculous Epididymitis.*—Tumours of the testicle frequently, though not invariably, arise in the neighbourhood of the rete testis, and growth may advance at an early stage into the mediastinum testis and the lower end of the spermatic cord so as to simulate an enlargement of the epididymis. Such cases are frequently mistaken for tuberculous epididymitis, and I know of no constant rule by which to distinguish them. The absence of beading of the vas deferens and nodular enlargement of the prostate by no means excludes tuberculous epididymitis, and a definite diagnosis may only be possible at operation. All doubtful cases should be submitted to exploration.

*Hydrocele.*—In cases of common hydrocele the question may arise, either on clinical examination or at operation, as to whether the testicle contains a tumour. While it is unwise to be dogmatic, it is safe to say that the association of a *large* secondary hydrocele with tumour must be an event of extreme rarity. John Hunter [23] said that he had never seen a case. By far the largest secondary hydrocele in this series contained 10 oz. of fluid. In cases like this last it is useful to aspirate the fluid in order to feel the testicle. But in most cases there is little fluid and the use of the exploring needle is entirely contra-indicated, for it provides no useful information.

### TREATMENT.

The benign typical teratomata can occasionally be dealt with by enucleation, but as a rule it is more satisfactory to perform orchidectomy. Orchidectomy has been, and still is, the treatment most generally employed for malignant tumours of the testicle, but the frequency with which the disease recurs in the lumbar glands has led surgeons to devise a more radical operation. In its present form this operation aims at the removal of testicle, spermatic cord, intra-abdominal spermatic vessels and lymphatics, and the lumbar glands, all in one piece. The operation was introduced into this country by Sir John Bland-Sutton [24] in 1909, and the time is ripe for us to inquire into its merits as compared with the more simple operation of orchidectomy. I propose, therefore, to place before you the results of the London Hospital series.

During the last 18 years, 1908–1925, 74 cases were treated by operation, 55 by orchidectomy, and 19 by the radical operation. All cases recovered from operation and were discharged from hospital. The after-results were traced up to the end of 1925 in all but six cases, with the assistance of the Registrar-General in 11 cases. Recurrence of the disease proved to be extremely rare after two years, and estimations on the basis of a three-year cure are, therefore, approximately accurate. One case in which death from influenza and broncho-pneumonia occurred over three years after operation has accordingly been regarded as a cure. Patients in whom the lumbar glands were already palpable on admission have been considered incurable, either by orchidectomy or by the radical operation.

*Table Showing Results of All Cases up to the End of 1922.*

| | Orchidectomy. | | Radical operation. |
|---|---|---|---|
| 1. Untraced .. .. .. .. | 5 | .... | 1 |
| 2. Lumbar glands palpable before operation .. .. .. .. | 2 | .... | — |
| 3. Died of metastases (excluding Group 2) .. .. .. .. | 24 | .... | 11 |
| 4. Died from other causes .. .. | — | .... | 1 |
| 5. Alive and well .. .. .. | 12 | .... | 4 |
| Total .. | 43 | .... | 17 |

From the table, which gives the results of all cases up to the end of 1922, it is seen that the rate of recovery is, after orchidectomy, 83·3 per cent., and after the radical operation 31·2 per cent. These figures are not quite comparable, for it so happens that relatively more spheroidal-celled tumours were treated by orchidectomy, whereas most of the cases treated by the radical operation were atypical teratomata, tumours of greater malignancy. It follows that the radical operation was set a harder test than the local operation.

On the whole, therefore, I am of the opinion that the results are slightly in favour of the radical operation. Yet it is questionable whether they are a sufficient improvement over the results of orchidectomy to justify the added risk. The London Hospital figures of 19 radical operations with no [illegible] a true indication of this risk, for the 77 cases reported or collected from the literature by Hinman and his associates[25] show an operative mortality of over 10 per cent.

There are certain a priori reasons against the radical operation. Handfield-Jones,[26] who has recently mapped out the lymphatic drainage of the testicle, has confirmed the conclusion of Jamieson and Dobson[27] that complete removal of the lumbar glands and lymphatics is a surgical impossibility. Again, the operation itself is so often disappointing: either there are metastases so closely adherent to the aorta or inferior vena cava that they cannot be removed, or there are no metastases, and the surgeon can find nothing to remove but the spermatic vessels and one or two small lymph glands—a very small amount of tissue for such a large operation. Hinman, however, has collected or described four cases in which the lumbar glands removed at operation were found to contain secondary growth. The patients were alive and well over four years after operation. These cases would probably not have been cured had they been treated merely by orchidectomy, though it is well to note that at present we have no definite proof that lymph glands are not capable of destroying small secondary deposits of tumour tissue.

This concludes the evidence for and against the radical operation. That it is meagre is not surprising when we recall that the operation has only been practised for 20 years and that the number of cases is small. I do not think, therefore, that we can with equity reach a final decision. The London Hospital cases show that the radical operation can be performed with no immediate mortality. In view of this and of the results so far obtained, I consider that the radical operation is warranted a further trial.

In this series treatment of metastases by X rays has been entirely unsuccessful. Some workers have reported good results from the use of radium, but of this I have had no experience.

In conclusion, I would like to thank the visiting staff of the London Hospital for permission to study their cases and for much helpful advice. The pathological material upon which this lecture is based has been collected and carefully recorded by Prof. H. M. Turnbull, director of the Pathological Institute of the London Hospital, and by his assistants, in particular Dr. W. W. Woods. To Prof. Turnbull I am deeply indebted for allowing me access to this material and for his constant inspiration and assistance.

# Lumleian Lectures
ON
# ENDOCARDITIS.

*The Third* Lumleian Lecture in 1926, delivered before the Royal College of Physicians of London on March 30th,*

BY SIR THOMAS HORDER, BART., K.C.V.O., M.D., F.R.C.P. LOND.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

I PROPOSE now to deal with the anatomical and bacteriological parts of my subject, and then with considerations of diagnosis, pathogenesis, and treatment.

### STATE OF THE VALVES PRIOR TO THE ONSET OF SEPTIC ENDOCARDITIS.

This is an important point. In my original series of 118 post-mortems in 150 cases I found evidence of old valvular disease in 80 per cent. The figures of other observers approximate very near to this. But it is to be noted that this figure refers to acute and chronic cases when taken together. If we consider acute cases alone the figure is undoubtedly much smaller. If we take the series of cases of ex-soldiers by themselves we find it smaller still. Thus, out of 13 autopsies in this class, Starling found scarring from old rheumatic disease in one only. Carey Coombs's experience is much the same. The inclusion of 20 cases of ex-Service men explains why, in a second series of 162 cases at St. Bartholomew's Hospital, the figure is only 50 per cent. Sir John Rose Bradford, in his Lumleian lecture in 1920, stated that, despite the prevalence of sepsis in the wounded during the great war, infective endocarditis was uncommon; that a number of acute and rapidly fatal cases of the disease occurred in men in whom no primary source of infection could be found post mortem; and that in these cases the infection had attacked healthy valves. Summing up, therefore, it may be said that in acute cases generally, and in the chronic ex-Service cases, there is a notable absence of pre-existing valvular disease; in chronic civilian cases there is a marked preponderance of pre-existing valvular disease. It has, perhaps, been too readily assumed that the nature of the pre-existing valve damage found at autopsy is generally rheumatic in origin. Care must be taken, as Libman has pointed out, to distinguish the residues of rheumatic infection from the residues of an old septic endocarditis, since it is now known that this latter process may recur after years of apparent freedom from active infection. The patient's history is, therefore, of great importance in judging the nature of cicatricial and of sclerotic changes in the valves. Since pericarditis is known to be quite rare in chronic septic endocarditis, evidence of this at autopsy is much in favour of old rheumatic infection. The type of myocardial disease, if this be present, may also assist in a correct interpretation of the findings.

Of the *valves affected* it is again important to distinguish acute from chronic cases and civilian chronic cases from ex-Service chronic cases. In acute cases the incidence of mitral and aortic disease is probably about equal. Of 34 such cases due to *Streptococcus pyogenes*, Thayer found the aortic valve involved in 20 cases, the mitral in 26. Gonococcal infection, however, tends to attack the aortic valve by preference. Thayer's cases, forming the fullest series of which we have details, showed 66 per cent. aortic and only 19 per cent. mitral. There were right heart lesions as often as mitral in this infection. Of 40 cases of pneumococcal endocarditis, Thayer found the aortic cusps involved in 20, the mitral in 13, and the valves on the right side of the heart in seven only, thus disposing of the fallacy that pneumococcal infection is prone to attack the right heart chiefly. In chronic septic endocarditis, however, there is a preponderance of mitral infections in civilian cases, and a still greater preponderance of aortic cases in ex-soldiers.

---

* Lectures I. and II. appeared in THE LANCET of April 3rd and 10th respectively.

*Mural Infection.*

Mural infection is, I believe, more common than is generally thought. I found instances of this condition in 52 per cent. of 118 post-mortems. Thayer's figure is as high as 84 per cent in chronic cases. Auricular infection is much more common than ventricular The occurrence of mural endocarditis is usually attributed to the influence of pre-existing scars from old rheumatic disease. The occurrence of mural lesions without valve lesions must be quite rare. I cannot find any case in the literature which is at all comparable with one which I described in my original series, and where, fortunately, a *post-mortem* examination was possible. The disease had lasted for over two years, the type being very chronic, the fever very mild There was no sign of valvular disease during life. This patient was for some weeks in a sanatorium on account of pyrexia, sweats, and malaise, it being thought that she might be a case of pulmonary tuberculosis without physical signs. She developed multiple infarction of the spleen and blood cultures were positive. Eventually she died of cerebral embolism. Post mortem there was found a small area of fungating auricular mural endocarditis, situated well above the mitral orifice, the cusps of which were natural. The importance of knowing that such cases exist lies in the fact that the disease may be present in the absence of signs of valvular mischief. But, as already stated, such cases are rare

PARASITOLOGY.

I pass now to a consideration of the parasitology of endocarditis. I need not dwell upon the infecting agent in the syphilitic cases, except to point out that all the evidence favours the view that the route of infection is by the vasa vasorum to the middle coat of the aorta, and that it is, therefore, probable that the aortic cusps are infected likewise from the depths rather than from the surface.

Nor must I dwell long upon the old controversy anent the *causative agent in acute rheumatism* Of late years there has been a growing tendency to consider the streptococcal origin of acute rheumatism as proved But clearly this is not so, and it seems to me that we do but obstruct further research by so premature a conclusion. With due deference to Poynton and Paine, whose thorough and masterly work all must admire, it is to be doubted if the real picture of acute rheumatism has yet been experimentally produced in animals by the use of the "diplococcus rheumaticus." Nor is there, so far, anything like unanimity amongst the many observers who have given pains to the question of blood cultures in rheumatic fever, and to the bacteriological investigation of fatal cases of the disease. Unfortunately, the opportunities for this particular research become less and less with the decrease in incidence of severe rheumatic fever, but when the disease was rife, and even now, when it occurs, the number of negative results in the hands of skilled bacteriologists were, and are, strikingly large And this, too, when the most approved culture methods are adopted. Such strains of cocci as are occasionally found in these cases seem to possess no special features, and considerable weight must be attached to the fact that the blood in cases of acute rheumatism has failed to yield any specific serological affinity, even for those homologous streptococci that have been isolated from the circulation of rheumatic patients. Such is the experience of Swift and Kinsella, who record the following striking case A streptococcus was isolated from the blood of a patient in a first attack of rheumatic fever. A relapse occurred after a year of good health, and a second streptococcus was this time isolated. The two streptococci differed culturally and serologically. No complement-fixing antibodies against the first streptococcus could be demonstrated in the blood at the time of the second infection. Clawson and Bell have quite recently claimed to obtain a streptococcus by blood culture in 50 per cent. of cases of rheumatic fever Yet they, again, failed to find antibodies in the blood at a serum dilution higher than 1 in 50. On the other hand, Clawson considers that he has produced lesions in rabbits' hearts which were morphologically identical with the Aschoff nodule by the use of rheumatic strains of streptococci. He therefore concludes that streptococci, generally of the viridans type, are responsible for rheumatic heart lesions in man. This vexed question must still be considered as undecided.

In *acute cases of septic endocarditis* the nature of the infection calls for no special comment. Positive blood cultures are forthcoming in nearly all cases, and, as already remarked, the micro-organisms are of a highly virulent type.

Until the rôle of the streptococcus in acute rheumatism is more clearly defined, whether, for example, it is the primary cause or only present in the disease as a secondary infection, we cannot profitably discuss the question if some of the cases of *chronic septic endocarditis* may not be justly regarded as cases of "malignant rheumatism" Such a conception is only rendered probable by assuming, with Poynton, that the rheumococcus remains latent in the endocardium for, it may be, many years. This seems less probable than that the disease is the result of a new infection grafted upon the old damaged valve, and this view is the one most generally accepted at present.

Positive blood cultures in the chronic cases are, as already mentioned, by no means invariable. In my early series of mixed acute and chronic cases I found micro-organisms in the blood in nearly 90 per cent. of cases at some stage of the disease. Libman gives the same figure for his cases. But in a second recent series of 102 cases at St. Bartholomew's Hospital the number of positive blood cultures was only 47 per cent. This was largely due to the inclusion in the series of a much larger proportion of chronic cases, and especially of 20 ex-Service cases; in these 20 cases the number of positive blood cultures was only 30 per cent. This paucity of positive cultures in the ex-Service class corresponds with the experience of other observers. The micro-organisms found in these cultures are almost entirely streptococci; the exception is the strange one of Pfeiffer's bacillus, which crops up with extraordinary constancy in the series of all observers provided the number of cases in any series be not too small.

There seems little reason to doubt that the cocci recovered from the circulation during life, and also those isolated from the diseased endocardium after death, by various observers have been of the same type, though called by different names. The difference in names has depended upon the different principles adopted in the segregation of the streptococcus and pneumococcus groups. My original description of these cocci was based upon Gordon's well known work, in which the morphological and cultural characters of these micro-organisms were supplemented by biochemical reactions in various sugars. Working in conjunction with Andrewes we were able to trace very close affinities between the streptococci associated with chronic septic endocarditis and the salivary and fæcal types as differentiated by Gordon. Schottmüller's nomenclature was based largely upon the fact that these streptococci reacted in a special manner on blood-agar plates; hence his term *Strep. viridans.* Rosenow, on grounds which need not be entered upon here, claimed to have obtained evidence that these comparatively non-virulent cocci are modified pneumococci, and that by frequent passage through animals, and by special anaerobic cultural methods, they could be converted into micro-organisms indistinguishable from pneumococci and possessed of considerable pathogenicity. I am unaware that this work of Rosenow's has been confirmed. Libman is content to term the coccus most commonly found in chronic septic endocarditis *Strep. endocarditidis.* But when we consider questions of pathogenesis it is obvious that the nature and origin of these streptococci become matters of great importance. Too much attention cannot, therefore, be paid by bacteriologists to the life-history of these cocci and to their probable source.

This is, perhaps, a convenient place in which to refer to Libman's views upon what he terms the "bacteria-free stage" of chronic septic endocarditis. I have already confessed my inability to accept Libman's concept of the disease we are now considering as being a "subacute" rather than a "chronic" process. I gather that others have the same difficulty. I find that the last edition of Osler and McCrae's text-book of medicine includes two separate paragraphs; one is headed "subacute bacterial endocarditis" and the other, immediately following it, is headed "chronic infective endocarditis." But Libman makes it clear that by introducing the term "subacute bacterial endocarditis" he intends it to supersede the older name of "chronic infective endocarditis," and to include the cases formerly put into this category. I must now confess to another inability to follow Libman when he uses the term "bacteria-free stage" of the disease as being synonymous with "healed stage." This writer speaks frequently of "healed and healing cases" in one and the same term. Now I can understand a "healed" case; there seems no doubt, largely as the result of Libman's own observations, that cases of septic endocarditis do occasionally undergo spontaneous cure, and that the residues of the old infection are found post mortem. I can also understand a "healing" case; in many chronic infections we get evidence, both during life and after death, that the lesions show constructive, as well as destructive, changes; to mention only pulmonary tuberculosis as one example. But to group "healed and healing cases" together under this single term seems to suggest some new type of case the criteria of which have been made by no means clear.

Libman admits that in the so-called "bacteria-free stage" of the disease some degree of pyrexia is often present, that anæmia is marked, that embolism goes on, that Osler's nodes and petechiæ appear, that the patients get progressively more and more toxic and eventually die. But is not this passage from a more active stage of the disease to a more passive stage exactly what we see in some, indeed, in a good many, other chronic infections? In chronic pulmonary tuberculosis, again; in lymphadenoma; in chronic *Staphylococcus aureus* pyæmia; in syphilis; in malaria. In chronic septic endocarditis, as in these other diseases, patients not infrequently reach a cachectic stage in which the infection peters out, as it were, at the same time as the patient. The fight has been to a finish and neither party has won. Actually, the micro-organism has won, but only just. It can generally be demonstrated, though perhaps with difficulty, dug in and out of sight. And Libman admits this fact. I instance *S. aureus* infections of a chronic kind in particular as giving us a somewhat similar picture to that which is sometimes seen in chronic septic endocarditis. After a long and tedious illness the patient, cachectic, wasted, anæmic, enfeebled by his prolonged toxæmia, dies exhausted. Blood cultures have been sterile for weeks, even months, and the temperature has been at a much lower level than formerly. At first we were jubilant when these things happened. But they availed nothing, and we became aware that though the fire of the interaction burned much lower the disease was still progressing. We make a post-mortem examination, perhaps; there is no obvious lesion; then, tucked away in some remote corner, we find a collection of inspissated pus—in the sheath of the psoas muscle, perhaps, or in the centrum ovale of the brain. From these old, but still smouldering, foci *S. aureus* is recovered in scanty numbers.

We must, of course, distinguish these so-called "bacteria-free" cases from the periods occurring earlier in the disease during which blood cultures are oft-times negative, yet the patient is obviously in an active stage of his infection. There are possible reasons for these times of relative, or perhaps absolute, a-bacteriæmia. (1) They may be due to the covering over of the colonised bacteria in the valve cusps by a layer of fibrinous material which, for the time being, prevents the paying out of cocci into the blood stream. (2) Or they may be the result of a rise in the bactericidal or other immunising antibodies in the blood, so that the circulation is rendered sterile within the limits of the amount of blood taken for purposes of the culture. Doubtless, there are other causes which are as yet hidden from us. Mervyn Gordon has raised the question whether there may not be some filtering mechanism at work; he also reminds us of the great tendency of bacteria to yield to gravity. I should like to add the suggestion that in these cases something akin to the process of centrifugalisation may go on, by which the bacteria, which are thrown into the circulation, are sedimented in various peripheral organs, leaving the blood stream relatively free. A close study of the cases makes it more and more apparent how innumerable are the embolic events that take place and, therefore, how consonant with actual facts such a hypothesis may be.

### DIAGNOSIS.

As the result of my earlier experience I was led to the view that to establish a diagnosis four cardinal points were necessary: multiple embolism, the signs of endocarditis, the isolation of a micro-organism from the blood, and pyrexia. Now that we are more familiar with the clinical picture, and have added certain other well-recognised signs, the diagnosis becomes highly probable, though perhaps never quite certain, without the third and certainly without the fourth of these features. Thus, signs of multiple embolism, with endocarditis, in a patient having clubbed fingers and an otherwise unexplained anæmia, constitute a syndrome which scarcely admits of any other conclusion. In arriving at a decision, however, it is well to remember what a very grave prognosis a positive diagnosis carries with it in the present state of our ignorance of effective treatment. No doubt we shall be able, in years to come, to detect the disease at an earlier stage of its course, in which case we must be satisfied with less severe criteria. It may even be desirable to treat many patients as suspects, and remain uncertain, in the event of a satisfactory issue, if they were, or were not, larval instances of the disease. In other words, we must strive to anticipate rather than merely to recognise, when present, the fully-developed picture. There are other very suspicious combinations of signs and symptoms than that just given, but granted that neither pyrexia nor a positive blood culture is essential to the diagnosis it is impossible at present to construct a syndrome that does not include the feature of multiple embolism. And it is questionable if, once this process is in operation, we are not already too late in our efforts to arrest the disease.

We do not know, unfortunately, if there is an early apyrexial stage in the disease. We certainly do know that, though every case is probably at some time in its course pyrexial, apyrexial periods of one, two, or even three weeks are by no means uncommon during the later stages. Starling tells of an extraordinary instance of prolonged apyrexia lasting 17 weeks. It is clear, therefore, that the absence of pyrexia at any particular time of observation by no means excludes the diagnosis.

Be the significance of negative blood cultures what it may, it is agreed that the diagnosis can frequently be made without evidence of bacteriæmia at the time of examination, and, indeed, even though one or more subsequent efforts are also negative. Libman has described localised tenderness over the lower end of the sternum with light pressure as a common symptom. I have found this present in several cases, but since I have also found it to be not uncommon in cases of severe anæmia, without evidence of endocarditis, I conclude that its importance in diagnosis depends upon the absence of this latter condition. Such tenderness is sometimes very marked and very localised in Addisonian anæmia.

We are beginning to see light on the clinical side, and also on the side of gross morbid anatomy, in relation to the earlier stages of the disease, and this light may soon help in the histological and bacteriological sides by suggesting new lines of research. Several authors have described cases of mild bacteriæmia, the cocci being of the same type as those associated with chronic septic endocarditis, and in which the clinical analogies with this latter disease are such as to suggest they may have been abortive cases of it. Some of the cases have been followed for a period sufficiently long to make sure that they have recovered. It is tempting to consider them instances in which, as it were, the disease, as we usually know it, has missed fire.

### *Recurrence.*

Cases of recurrence, too, are being brought to light. I have seen two such cases. In one of these I was very doubtful, when the patient first came under observation, if I was not dealing with a case of septic endocarditis. There were signs of aortic regurgitation, and the patient was admitted to hospital on account of mild pyrexia, purpura, and arthritis. The spleen was palpable. Blood cultures were negative. The man was an ex-soldier with no history of any cause for his valvular disease. After two months' observation he was discharged, being given the benefit of the doubt. He worked continuously as a postman for 12 months, feeling quite well. He was then admitted again to hospital, pyrexia and joint pains of an erratic kind having returned. The diagnosis of chronic septic endocarditis did not now admit of any doubt. In the other case there was again a clear interval of 12 months of good health between an attack of right hemiparesis associated with mitral regurgitation, slight pyrexia, clubbed fingers, and anæmia, and a second admission on account of a left hemiplegia, which was followed a month later by cerebral hæmorrhage.

It is possible, of course, that in neither of these cases was the interval between the two periods of observation sufficiently long to exclude the question of very protracted infection with unusually long remissions. But Libman and others have reported cases in which the interval between the attacks has been much longer. So that, unless we again take the view that the coccus can lie dormant in the endocardium over a period of years, we must consider the cases as true reinfections.

## PATHOGENESIS.

When we turn to questions of pathogenesis we are faced with a whole series of unknown factors. We seem to know a good deal about the mechanism of the disease once the endocardial infection is established, and even our knowledge of the associated bacteria is by no means small, but the initial phases in the process of endocardial colonisation are still hidden. We assume, perhaps rather too readily, that the source of the invading and infecting bacteria is one or other of the areas which for convenience we term areas of "focal sepsis." Such areas are conceived of as portals of entry of bacteria into the circulation. These areas have been recorded in many cases of the disease as though the relation between them and the heart infection were actually proved. Blumer has collected these records. It does not surprise us to read that the teeth and the tonsils head the list, that the female generative organs come next, and that the bronchial tract follows. But between the very common finding of salivary streptococci in apical tooth abscesses and the relatively uncommon finding of salivary streptococci in the endocardium there is a wide gulf to bridge. With the whole alimentary tract teeming with streptococci of this and of allied types, it is quite a question if the area of focal sepsis is more than an epiphenomenon in the process of deep-seated infection.

### *Mechanism of Invasion of Valves.*

If we now consider the mechanism of invasion of the infected valve we are equally in the dark. Does the coccus invade the valve from the coronary route or from the general blood stream bathing the outside of the valve? The argument for and against both routes, though old, is still open. Carey Coombs has quite recently convinced himself that, whereas the rheumatic virus reaches the cusps, and produces a valvulitis from within these structures, the bacteria in septic endocarditis attack them from the blood circulating around the cusps. The author's important work in connexion with the endocarditis of swine erysipelas is adduced in support of his views. But we still lack adequate demonstration of this difference of the modes of invasion in the two diseases. Whereas some authors adduce the fact of extravascularisation resulting from old inflammation as evidence that the coronary route is the likely one in septic endocarditis, others consider the scarring of the tissues resulting from the same process as liable to favour invasion from the surface. Certainly, if analogy elsewhere goes for anything, it seems more likely that scarred tissues in this situation would be invaded from the surface rather than from the depths. But this latter hypothesis presupposes an initial septicæmia, or at any rate a bacteriæmia, and probably of a massive kind. Of this there does not seem to be any clinical evidence; the disease is very insidious in its onset in nearly every case. Moreover, we are now faced with a difficulty with which the war cases have for the first time familiarised us—namely, that in many of these cases there appears to have been no old valve injury, or none the existence of which was apparent. Yet when we recollect that it is in the hearts which possess minor valve injuries, and not in those in which the valves are seriously damaged, that by preference the disease develops, we must pause before we conclude that the aortic cusps in these ex-soldiers were above suspicion. In this connexion are to be considered the remarks already made concerning congenital defects, such as fusion of cusps, and the effects of strain upon such mechanically handicapped structures. It is rather a terrible thought, and yet it may well be true, that starting life with two aortic cusps instead of three determines a man's ultimate downfall by means of slow but inevitable sepsis, be the conditions of his life what they may. There are many persons in the possession of relatively good health who have minor degrees of valvular disease with good myocardial tone. Is there any way of ascertaining which of these are to be regarded as candidates for endocardial infection? At present the answer is that there is no such way. It is a point worthy of consideration, for if some observations arose by which such predisposition may be recognised this would be a matter of great importance.

But if we are still much in the dark concerning the mechanism of the valve invasion and colonisation, we are still more in the dark as to why it is that such feebly virulent bacteria gain so firm a foothold and pursue such relentless warfare. Is it mainly the general resistance that is at fault, or is it mainly the local tissue resistance? Does the coccus succeed in immunising itself against the natural protecting substances of the blood and tissues? These are some of the questions that still await our answers. To which may be added the fact that the process of chronic ulceration in general in the body still holds some mysteries we have never yet explained.

### *Is Septic Endocarditis a Specific Disease?*

I have spoken of one great contrast between rheumatic endocarditis and septic endocarditis—namely, the great tendency to early and considerable involvement of the heart in the former and the great freedom from intrinsic disease of the heart in the latter condition. I now turn to another great difference between these two diseases. In rheumatic heart disease we feel convinced that we are dealing with the work of a specific agent, and this conviction is not shaken by some doubt as to the causative nature of the infecting agent in certain cases of mitral stenosis. In septic endocarditis, on the other hand, we appear not to be dealing with a specific disease at all—that is, if we are right in our conclusions that the micro-organisms found to be associated with the disease during life and in the post-mortem room represent the only infecting agents present. I say this because, although I do not know that anyone has advanced evidence for such a view, it is just possible that all the bacteria associated with the pyæmic state in which the endocardium and various peripheral organs are concerned are of the nature of secondary infections, the primary infection being as yet unknown and hardly suspected. But if we assume that the micro-organisms that we deal with every day in the disease are the sole causes of the infection, then we are faced with this striking fact—that the same disease picture may be produced by a variety of different micro-organisms. Even if it be argued that Rosenow's conclusions relative to the association of pneumococci with the disease are not yet accepted, and that the gonococcus cases are not really chronic (though two patients in Thayer's series lived over six months), there still remain, in addition to the streptococcal cases which bulk so largely in the whole number, the cases due to Pfeiffer's bacillus. Between these last-named cases and those due to streptococci there cannot, so far as I know, be distinguished any difference either clinically or by naked eye morbid anatomy. And yet we know of no affinities whatever between the streptococcal group of micro-organisms and the group of which *B. pfeiffer* is a prominent member. But the lack of specificity in the disease would appear to go further than this. Individual cases within the streptococcal group show a strange lack of uniformity when investigated serologically. Kenneth Stone, working in Gordon's laboratory upon complement-fixation in streptococcal infections, found that the serum from cases of chronic septic endocarditis gave positive reactions with the homologous cocci obtained by blood culture, with a titre even as high as 1 : 4800, but that this same serum gave very little cross fixation with heterologous cocci (that is, with cocci obtained from other cases), and frequently no cross fixation occurred at all. It would almost appear, therefore, as though the cases, far from being specific as a group, are specific only as individuals. The bearing of all this upon the difficulties of immune therapy is obvious.

There is still, it seems to me, another striking fact in connexion with the bacteriology of the disease, and that is the absence of any evidence that more than one strain of streptococcus is present in the same case. Nor has any case yet been described in which streptococci and Pfeiffer's bacillus have both been present. If the source of the endocardial infection is an area of focal sepsis, as is commonly supposed, it seems strange that there should not occur in the vegetations and in the circulation, at least occasionally, more than one strain of these common invaders. That this is so strongly favours the view that the streptococci are not performing the rôle of secondary, but of primary, infections.

### Treatment.

I shall not stay to deal with the treatment in cases of syphilitic disease. In rheumatic endocarditis the treatment is that of acute and recurring rheumatism. Into this again I shall not go, reserving my time rather for considerations that apply to septic cases. When faced with a case of acute infective endocarditis the treatment is that of the septic focus, when this is present, and also of the pyæmia complicating it. Immunotherapy has, perhaps, a slightly better chance of rendering assistance here than it has in chronic cases; it should, therefore, be given a thorough trial. The vogue at present is the process known as immuno-transfusion, and it is, perhaps, too early yet to say what the results of this method are. All cases should, wherever practicable, be treated in the open air.

I now turn to the treatment of the chronic type of septic endocarditis.

#### *Prophylactic Measures.*

In one of his most recent communications Libman is good enough to credit me with being the first to emphasise the importance of *prophylactic measures* in the treatment of this disease. Although there is no doubt he is correct in this, he is kind enough not to point out the paucity of the constructive suggestions which I made under this heading in 1909. I dealt almost entirely with the importance of treating the various forms of oral sepsis, and with considering certain methods by which the streptococci of the intestinal tract might be kept from transgressing the barriers which usually suffice to keep them outside the blood stream. That these measures of preventive treatment are of more importance in patients who have residual endocardial lesions, of whatever origin, than in other persons will scarcely be questioned. Yet it is by no means an uncommon experience to find devitalised teeth with demonstrable apical sepsis in these patients. The well-established sequence of a septic endocarditis arising as a direct consequence of the extraction of such teeth under local anæsthesia, together with the isolation of a salivary type of streptococcus from the blood in such cases, should surely lead to a rule of treatment by the observance of which no dead teeth and no obvious pyorrhœa are permitted to be present in such patients. It is unfortunate that a recent obsession in regard to sacrificing all teeth that are in the least degree suspicious in every patient has militated in the public mind against such a preventive measure being followed in selected cases. The question of septic tonsils is much less simple, because the criteria by which we judge these organs are notoriously vague, whether we consider the matter from the point of view of the general physician, the throat specialist, or the bacteriologist. Tonsils are sometimes condemned because cultures taken from them grow streptococci of the hæmolytic, long-chained, or pyogenes type, on the ground that this is a more highly pathogenic type than others. But it is obvious, from what has been said, that in the present connexion such a finding should not condemn the tonsils any more than if the cultures yielded the viridans, short-chained, or salivary type; if, indeed, the condemnation should be as strong. The present state of our knowledge of the streptococcus group makes the statement so often occurring in bacteriological reports, that "cultures from the tonsils give no pathogenic strains of streptococci" of no service when we are considering the prophylactic treatment of endocarditis. Until we have more definite guidance along these lines we shall probably act most wisely by deciding the question of the enucleation of tonsils on their general merits rather than upon their bacteriological content.

In the direction of "intestinal disinfection," so-called, prophylaxis gropes in even greater darkness. There are problems here which we have scarcely begun to probe, but to think that security from subinfection lies in merely avoiding constipation, good though such advice may be, is to invite a rude awakening. We do not even know for certain that subinfection from the bowel bears any definite relation to the quantitative content of streptococci in this situation, or to the relative proportions of streptococci to coliform bacilli, though both of these things are generally taken for granted. Is it not a fact that we not infrequently make use of these and analogous findings to support a scheme of therapeutics, when the premises upon which such a scheme is based are quite lacking in proof? The suggestion of Besredka and others, that it might be well to employ antigens by the intestinal route in cases in which it is presumed that the initial interaction resulting from infection takes place in this situation has scarcely received so thorough a trial as it deserves. We may get some help from such a trial. We may also get some help from well-controlled observations relative to the effect of different diets upon the intestinal flora. Up till now very little work has been done on this point.

The injunction against undue strain, both physical and emotional, in persons having evidence of slight valvular defects, though indicated theoretically, is not likely to carry much weight. Yet it becomes our duty to give such advice in view of all the facts.

*Curative Measures.*

Curative measures now call for consideration. *Chemotherapy*, despite the enormous number of drugs that have been tried at one time or another and which I will not stay to catalogue, has so far been of little real help. And this is true by whatever route the drugs have been used. Yet it must not be concluded that we shall not ultimately find some remedy of a chemical nature which shall assist the tissues in their interaction with the infecting agent; for the crude notion that a chemical remedy can only help in microbic infections by a direct bactericidal action is, of course, no longer tenable. Of late years new claims have been made on behalf of arsenic, and especially when given intravenously. Needless to say, when the arsenobenzol series of drugs arrived they were given full trial in septic endocarditis, but, so far as I can find, without any permanently good results. Of immediately serious results by way of cerebral embolus I saw not a few, and I gather this is the experience of others. I have given Capps's sodium-cacodylate treatment a very thorough trial, but have so far seen nothing to lead me to the conclusion that the patient has benefited more than is usual with so good a hæmatinic remedy as this proves to be in many infections. Capps gives daily injections of the drug intravenously, beginning with 1 gr. and increasing gradually up to 5 gr. In all I have treated 12 cases, and I have in half of these given larger doses than Capps has recommended. I have also, following Capps's suggestion, followed up the treatment for many weeks. There is certainly this to be said for the drug, that it is singularly free from ill-effects.

I think it is clear, from all we know of the disease, that recovery, whether by the aid of remedies used or occurring spontaneously, must of necessity be very slow if it is to be safe. When we remember the characters of the vegetations, and the ease with which they separate off as emboli it is obvious that any remedy which acted as quickly as, for example, a grand lavage of the blood stream by some reputed blood antiseptic, would endanger death from cerebral embolism. And when we recollect the deep colonisation of the infecting micro-organisms in the valves, it is equally obvious that no such lavage is likely to dislodge or kill these, seeing they are to a large extent outside the direct blood stream.

As little credit can be given so far to measures of *immunotherapy* as to those of chemotherapy. And this applies to all the permutations and combinations of antigen and immune serum that the mind of the immunologist—not a mind lacking in fertility and inventiveness—has so far devised. The latest of these is immuno-transfusion, which, though it is claimed that this method raises the bactericidal power of the blood, has not so far been more successful than other methods. A method of treatment which raises the bactericidal power of the blood as tested outside the body gives us no guarantee that it will do this inside the body; or, if it does, that the rise in bactericidal power will be sufficient, within the limits of the method, to turn the scale against the infecting agent and in favour of the patient. These things would be very puzzling did we not know of stranger facts. The fact, for example, that, apart from any immune therapy whatever, the blood in many cases of chronic septic endocarditis is extremely rich in certain antibodies specific to the micro-organism isolated from the patient's circulation. And yet such patients may, all the time, be losing ground slowly but surely.

In opening a discussion upon chronic septic endocarditis at Cambridge in 1920, when speaking of curative treatment, I raised the point as to whether we ought not to deal with these patients on much the same lines as we follow in cases of chronic tuberculosis, bearing in mind, of course, the difference in the organs affected. I have of late years concentrated more and more upon non-specific measures as for a disease of "low resistance." I treat as many cases as possible in the open air, with sunlight, natural and artificial. I supplement this by a long series of intravenous and intramuscular injections of sodium cacodylate. Sometimes I have found, as others have, that simple transfusions of blood are of considerable help. These are the only measures I yet know of that seem to give the patients the best chance of overcoming their usually intractable infection.

It remains for me to thank you, Sir, and the Fellows, for your patience in giving me your attention during the delivery of these lectures.

# THE
# SERUM TREATMENT OF DIPHTHERIA.

*Being a Paper read before the Fever Hospital Medical Service Group of the Society of Medical Officers of Health on Jan. 22nd, 1926,*

BY DONALD MACINTYRE, *M.C.*, M.D. GLASG., D.P.H. LOND.,
MEDICAL SUPERINTENDENT, PLAISTOW HOSPITAL.

IT is just over 30 years since antitoxin was discovered for the treatment of diphtheria, and it may be of interest to take a brief review of the results obtained with it and the progress which has been made in our methods of administration. For the first few years after its introduction in 1894 the serum used was often of uncertain strength and the dosage, according to our present standard, was very small; but in spite of this the results obtained were very definite, as shown by the improvement of patients after injection and the marked decrease in the case mortality. Physicians all over the world were soon impressed with the value of antitoxin, and its wide employment quickly revolutionised the former methods of treatment, especially the application of strong antiseptics to the local lesion, a procedure which, as now realised, must often have done more harm than good. The results obtained in those early years were sufficiently marked to convince the majority of physicians that in antitoxin we possessed a specific by which it was hoped diphtheria would soon be robbed of most of its terrors as a dangerous disease.

However, after 30 years' experience, during which antitoxin has been extensively used, we find that diphtheria still causes a large number of deaths in this country every year. And in comparing the deaths in 1924 with the number registered from the disease in 1871 we find that the decrease has been very small. Also, if we compare diphtheria in this respect with scarlet fever and typhoid fever, we find that during the past 54 years a much more marked and progressive fall has occurred in the annual deaths from these two diseases than from diphtheria. These figures are given in Table I.,[1] an examination of which shows that a continuous fall occurred in the mortality from scarlet fever and typhoid fever from the decennial period 1871–80, whereas the number of deaths from

diphtheria increased and reached a maximum during 1891–1900—the period during which antitoxin was introduced.

Comparison of this nature, however, is not a fair criticism of the value of antitoxin. We know that scarlet fever has become much milder in type of late years and that the prevalence of typhoid fever has greatly diminished, and these factors mainly account for the diminished death-rate from these two diseases. A better idea of the value of antitoxin is obtained by comparing the case mortality of these diseases, and in Table II.[1] I have shown the notifications for the past 14 years with the case mortality of the three diseases calculated per 100 notifications. From this it will be seen that the notifications of diphtheria have not varied much during the past 14 years, but the case mortality shows a much greater fall than has occurred with the other two diseases.

Case mortality rate calculated per 100 notifications.

It is a matter of no little difficulty to prove scientifically that antitoxin is a specific cure for diphtheria, as the fall in mortality rate since its introduction may be due to some extent to other factors, such, for example, as have led to the diminished death-rate from scarlet fever and typhoid fever. There are still a few medical men who do not consider the injection of antitoxin to be proper treatment for diphtheria, but their number is so small they can be disregarded.

There are also some who attribute the success of the treatment to the serum itself and not to any specific antitoxin contained in it. Claims have been made that equally good results[2] can be obtained with normal horse serum. A possible explanation of this view is that normal horse serum appears to have a stimulating action in some toxic and septic cases, and it is said to encourage phagocytosis. In this connexion I should like to say that in a number of cases which have been admitted to hospital as diphtheria but proved to be septic throats I have often noticed that the condition cleared up very rapidly after an injection of antitoxic serum, and I have been informed by several medical practitioners that in their experience serum injection appeared to clear up septic throats very rapidly.

There is, however, no proof that normal serum can take the place of antitoxic serum in the treatment of diphtheria. As regards the specificity of antitoxic serum, there is fortunately a sufficient mass of evidence available for one to affirm that it is of the utmost value in the treatment of diphtheria and should be administered to every case except perhaps the mildest. One item of this evidence which statistics prove is that antitoxin is of the greatest value when given early in the disease and that its efficacy diminishes with every day of delay in its administration. It can, I think, be safely stated that if all cases could be given an adequate amount of serum on the first day of disease the mortality would be reduced to nil.

### *Severity and Dosage.*

There is universal agreement about the importance of early treatment, but as to what constitutes an adequate amount of serum for any given case is a question on which there is still great diversity of opinion even among experts who have had many years experience of the treatment. One of the chief reasons for this is the absence of any definite sign or symptom by which one can be guided with any degree of certainty in estimating dosage. The amounts recommended in the literature for the different types of case are what individuals have found from experience to be sufficient. Unfortunately, however, the disease appears to vary in prevalence and in severity in different countries, in different areas of a country, and at different periods in the same area. Thus a scale of dosage which might be sufficient for the type of case prevalent, say, in the North of England, might not be adequate for the type prevalent in London. Table III.[1] shows the prevalence of diphtheria in different parts of England and Wales during the period 1911–20. From this it will be seen that the disease became more prevalent in London during the latter half of that period than in any other part of the country, and possibly also may have been of a more severe type.

TABLE III.—*Notifications of Diphtheria in the Years 1911–20. Rates per million.*

| Year. | London | Southern Co. | E. and Mid. Co. | N.W. Co. | Northern Co. | Wales. | England and Wales. |
|---|---|---|---|---|---|---|---|
| 1911 | 1637 | 1338 | 1267 | 1071 | 1423 | 1302 | 1324 |
| 1912 | 1572 | 1491 | 1125 | 961 | 1213 | 1208 | 1239 |
| 1913 | 1696 | 1552 | 1328 | 1104 | 1435 | 1404 | 1392 |
| 1914 | 2018 | 1686 | 1634 | 1177 | 1535 | 1540 | 1592 |
| 1915 | 2110 | 1679 | 1409 | 1136 | 1418 | 1428 | 1514 |
| 1916 | 2063 | 1456 | 1526 | 1261 | 1366 | 1349 | 1428 |
| 1917 | 2059 | 1308 | 1295 | 1105 | 1042 | 895 | 1284 |
| 1918 | 2066 | 1302 | 1246 | 1247 | 1096 | 965 | 1305 |
| 1919 | 2181 | 1471 | 1475 | 1265 | 1410 | 1207 | 1496 |
| 1920 | 3052 | 1836 | 1834 | 1341 | 1525 | 1930 | 1857 |

It is agreed among most experts that the size of the dose should be determined by the severity of the case irrespective of the age of the patient, and for this purpose the cases can be conveniently classified into mild, moderate, severe, and very severe. But here again individuals differ as to what constitutes a moderate or severe case. It is commonly stated that the amount of membrane present is the best guide to severity. This, however, is a variable feature. In very severe cases there is often so much swelling of the surrounding tissues that little or no membrane is visible, and when the posterior nares are involved it is impossible to see how much membrane is present. A better indication of severity in faucial cases is obtained from the extent of the tissue swelling, enlargement of the cervical glands, œdema of the neck, presence or absence of nasal discharge, and the appearance of the patient—i.e., whether he looks toxic or not.

The day of disease has also to be taken into consideration and the dose should be liberal for "late" cases; but beyond this the duration of the disease is not of very much assistance in the matter solely of estimating dosage. It is well known that in very severe cases coming late under treatment little or no benefit is often obtained even with a massive dose of antitoxin. Mild cases, on the other hand, usually only require a moderate amount of serum even though the disease has been of several days' duration. Thus the size of the dose should be gauged almost entirely by the severity of the case at the time it comes under treatment.

At this stage it may be convenient to refer to the scale of dosage recommended by four well-known authorities—viz., Park[2] (New York), the late Dr.

---

[2] Diphtheria, Medical Research Council, 1923, pp. 166, 258, 259.

Ker[3] (Edinburgh), Thomson[4] (London), and Madsen[5] (Copenhagen). There is not a very great deal of difference between the scales recommended by Ker and Thomson except that the amounts advocated by Ker are on the average slightly smaller. This might possibly be accounted for by a difference in the type of disease prevalent in Edinburgh and London. Their scales range from 2000 to 50,000 units according to the severity of the case, and this may be taken as fairly representative of the dosage employed in this country. Park, in his scale, draws a distinction between the amounts necessary for children and adults. His maximum for a child under 15 years is 20,000 units, and 50,000 units for an adult. In this respect he differs from most authorities in this country who, on account of the greater fatality of the disease among children, more or less disregard the age of the patient in gauging the dose. Also I doubt if 20,000 units would be considered in this country an adequate amount for a child, say of 5 years, who was suffering from a very severe attack of faucial diphtheria. Madsen, again, differs from the other three authorities in advocating massive doses, over 200,000 units, for the most severe cases. He states that a relatively small amount of serum will suffice to neutralise the toxin circulating in the blood at the time of injection and check later intoxication, but that in order to obtain what he terms a "curative action"—i.e., detach toxin which has loosely combined with the tissues—it is necessary to give huge doses. In support of this claim he shows that after Prof. Bie had commenced to employ massive doses at the Blegdams Hospital the case-mortality was reduced to under 1 per cent., which is very low as compared with the rate in this country.

It is, of course, the very severe cases that furnish the majority of deaths in diphtheria, and the question arises: Can a larger proportion of these be saved by giving massive doses? This, unfortunately, is most difficult to prove. Some cases are admitted periodically to fever hospitals which are so severe and "late" that one feels sure that no amount of antitoxin would save them. In support, however, of the claim for large doses it may, I think, be safely stated that when a patient receives a liberal dose of antitoxin the symptoms subside more rapidly and there is less risk of paralysis than when the amount given has been on a small scale. As is well known, it is difficult to give an overdose of serum, and the only real argument against using large doses is the expense. If, however, economy is exercised in the dosage for mild and moderate cases one, I think, is justified in employing large doses, say in the neighbourhood of 100,000 units, in the hope of saving a number of the most severe cases.

### *Dosage and Mortality.*

I should like here to refer briefly to the scale of dosage employed at Plaistow Hospital and the results. In Table IV. I have shown the number of admissions, deaths, and fatality rate of the diphtheria cases treated since the hospital was opened 30 years ago.

It will be seen that the annual admissions show a more or less steady increase which became more marked during the war. Since then the numbers have remained high. The deaths, on the other hand, show marked fluctuations, the highest number, 82, being reached in 1907, after which there was a drop to 24 in 1913. The numbers rose again during the war and remained high until three years ago, when a marked drop occurred, the lowest figure, 18, being reached last year. The fatality rate also has varied, but shows a continuous fall in the past few years. These fluctuations in the annual number of deaths are to be accounted for mainly, I think, by periodic variations in the type of the disease.

During the past three years, though the disease has remained prevalent, the type has become milder. And I must add that in the areas where it has been most prevalent the public appear to have become more alive to the dangers of diphtheria. In recent years it has become a common practice for parents to bring children with suspicious throat affections direct to the hospital if they have any difficulty in obtaining the service of a general practitioner. The number of cases admitted "late" through neglect of relatives in seeking medical advice has diminished. A few years ago we commenced to examine swabs for the medical practitioners, but I cannot say that this has affected the mortality from the disease. Two of the deaths last year were indirectly due to swabbing. In these two cases the practitioner swabbed the throat on first seeing the patient, but the swab proved negative, and it was not until about three days later, when the condition became very obvious, that the patient was admitted. I think there is a definite risk that if a practitioner gets into the habit of swabbing all suspicious throats he will soon become unable to diagnose diphtheria from its clinical signs and symptoms.

TABLE IV.—*Plaistow Hospital. Admissions, Deaths, and Fatality Rate from Diphtheria during the Past 30 Years.*

| Year. | Admis. | Deaths. | Fatality rate. | Year. | Admis. | Deaths | Fatality rate. |
|---|---|---|---|---|---|---|---|
| 1896 | 114 | 23 | 20·17 | 1911 | 295 | 52 | 17·62 |
| 1897 | 163 | 21 | 12·88 | 1912 | 291 | 35 | 12·03 |

| 1899 | 300 | 49 | 16·33 | 1914 | 380 | 43 | 11·31 |
| 1900 | 269 | 36 | 13·38 | 1915 | 403 | 60 | 14·88 |
| 1901 | 310 | 66 | 21·29 | 1916 | 533 | 64 | 12·00 |
| 1902 | 431 | 72 | 16·70 | 1917 | 559 | 67 | 11·98 |
| 1903 | 334 | 48 | 14·37 | 1918 | 464 | 70 | 15·08 |
| 1904 | 351 | 31 | 8·83 | 1919 | 601 | 57 | 9·48 |
| 1905 | 438 | 53 | 12·10 | 1920 | 700 | 62 | 8·20 |
| 1906 | 421 | 70 | 16·67 | 1921 | 560 | 32 | 5·71 |
| 1907 | 412 | 82 | 19·90 | 1922 | 611 | 40 | 6·54 |
| 1908 | 373 | 47 | 12·60 | 1923 | 671 | 23 | 3·42 |
| 1909 | 337 | 35 | 10·38 | 1924 | 713 | 27 | 3·78 |
| 1910 | 260 | 45 | 17·30 | 1925 | 719 | 18 | 2·50 |

Population served by the hospital: 1891, 201,905; 1901, 267,385; 1911, 289,030; 1921, 300,860; 1924, 317,400. The fatality rate is calculated per 100 admissions.

As regards dosage, up to the year 1914 the general routine dose was 2000–12,000 units, given by subcutaneous injection and repeated up to a maximum of about 40,000 for the most severe cases. In 1914 the intramuscular route was substituted for the subcutaneous, but the scale of dosage remained much about the same until 1920, when the disease increased in prevalence and severity and the maximum was increased to about 80,000 for the most severe cases. Since then our maximum has ranged from 70,000 to over 100,000 units, given partly by intravenous and partly by intramuscular injections. But during the past three years, as the type of disease became milder, our average dose diminished. In 1920–22 it worked out at about 28,000 units, but dropped in 1923 to 19,000 units. In 1924 it was 18,000 units and last year 15,000 units. At the beginning of last year our scale of dosage worked out at 9000 units for mild cases, 20,000 for the moderate, 40,000 for the severe, and 90,000 for the most severe. Last October we reduced this scale to 5000 units for the mild cases, 15,000 for the moderate, and 32,000 for the severe; but we made no change in our *maximum* for the most severe type. In comparing the results from 200 cases treated with each of these scales we found no appreciable difference in the mild type, but in the moderate and severe cases treated with the small scale the throat lesion did not clear up so rapidly, albuminuria was more common and persisted longer, and the paralysis rate was slightly increased. Our impression has been that the latter scale is the minimum that can be employed with safety.

### *Methods of Administration.*

The routes by which serum has been given have been by mouth and rectum, and by injections subcutaneously, intramuscularly, intravenously, intraperitoneally, and intrathecally. Administration by mouth and rectum has been shown to be practically valueless for therapeutic purposes and should not be employed.[3] Subcutaneous injection was the method most generally used in the early years of serum treatment and it still continues to be the common mode of administration. Its advantages are that it is safe and easy to perform. It has, however, one important disadvantage—namely, that the antitoxin is very slowly absorbed from the subcutaneous tissue.

---

[3] Ker, C. B.: Infectious Diseases, 1920, p. 431.

[4] Thomson, F. H.: Diagnosis and Treatment of Infectious Diseases, 1924, p. 137.

[5] Madsen, Th.: Journal of State Medicine, March, 1923, p. 101.

Intramuscular injection was first employed in this country about the year 1914, and it has now largely superseded the subcutaneous route. Its great advantage over that route is that the antitoxin is absorbed much more rapidly from muscular than from subcutaneous tissue—a very important consideration in severe cases. When the injection is made on the outer side of the thigh, in its middle third, it is quite as easy to perform, quite as safe, and less painful than subcutaneous injection in the abdominal wall. I do not know of any reason why the subcutaneous route should still be employed in preference to the intramuscular. The injection is sometimes made into the gluteal region, but this is a bad site as it is very painful and uncomfortable for the patient, and the puncture wound is liable to be infected.

Intravenous injection has the advantage over the other two routes in that the full effect of the antitoxin is obtained almost immediately. Its disadvantages are that the injection is frequently followed by a severe reaction and that in young children it is sometimes difficult to get the needle into a vein. From my own experience of this method in severe cases I have been impressed by the rapidity with which the toxic symptoms have subsided and by the number of patients who escaped paralysis or only had it slightly. Though the reactions following the injections are sometimes severe, death has been rare and with some practice the injection is not very difficult even in young children. In very severe cases I think an intravenous injection of part of the serum at the outset improves the patient's chance of recovery.

I regret I have had no experience of intraperitoneal and intrathecal injections and can offer no criticism of these two routes.

Regarding the question whether the antitoxin should be given in a single or repeated doses the evidence appears to show that one should aim at giving at the outset of the disease all the antitoxin the patient is likely to require. It has been stated that an insufficient first dose cannot be wholly compensated for by later injections. Some authorities favour repeated injections, and in severe cases it is often difficult to estimate at the outset the exact amount of serum the patient is likely to need.

In recent years brands of highly concentrated sera have been obtainable on the market and it is claimed for these that owing to the small bulk a large amount of serum can be injected more easily and that serum sickness is less likely to be severe than with unconcentrated brands. A highly concentrated serum should be very convenient to the general practitioner, but there does not seem to me to be any necessity for using it in hospital practice. I have found no difference between concentrated and unconcentrated brands in the incidence of serum sickness, and on the whole I prefer the unconcentrated type.

With reinjection of patients who have previously had serum the incidence of anaphylaxis or severe serum sickness is so rare, particularly in children, that the fear of it occurring need not prevent a second injection if the patient requires it. And it also seems unnecessary to give a desensitising dose to children.

### *Conclusions.*

Experience has shown that the value of antitoxin as a specific cure for diphtheria is limited to the early days of the disease—i.e., to the first three or four days from the onset. In order to reduce the case-mortality the first essential is early diagnosis and treatment.

Extensive swabbing of all suspected throats cannot be recommended because it incurs delay and the results are not always reliable. Better results would be obtained if medical practitioners made it a routine habit to inject all suspicious cases with antitoxin at their first visit on the scale recommended by the Ministry of Health.

For the type of case which is virulent from the onset I recommend the administration of large doses of serum partly by intravenous and partly by intramuscular injection.

---

# ON A METHOD OF CANCER RESEARCH.

BY HASTINGS GILFORD, F.R.C.S. ENG.,

FORMERLY HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE object of this article is to call attention to a method of research which has proved successful in the solution of some difficult problems of science and, for reasons which will presently be given, seems pre-eminently fitted for the solution of the cancer problem. It affords a strong contrast to methods of research now in vogue. These are inductive and seem to be based on the proposition that despite the possession of an enormous quantity of facts, the accumulation of centuries of observation and experience, we still lack the essential data. For these we search chiefly by experiments on lower animals in laboratories. The method now to be discussed is deductive. By it we assume that we already have facts enough and that we know the biological laws and the principles by means of which we can put them together in the right way in order to gain our end. The two methods are fundamentally different. By the former or inductive method the problem is approached as a locked-up mystery, a sort of Aladdin's cave, to be opened by means of a key, by some formula still to be found. By the deductive method, about to be described, it is regarded as a jig-saw puzzle on the grand scale, not to be solved until every part has been fitted together in its proper place.

Owing to the wonderful success of the experimental method when applied to other departments of medicine, induction is now so much more highly esteemed than deduction that there is reason to fear that its popularity is leading to its use in unsuitable cases. In reality each has its advantages and each should be regarded as complementary, not antagonistic, to the other. At no time has progress in knowledge been so rapid as when the one has gone hand in hand in friendly relations with the other, checking its exaggerations and correcting its mistakes. Hence the present dominance of experiment over experience, of laboratory work over general biological study, is matter for grave apprehension, and the time seems ripe for a general review of the situation and the trial of some wide method of deduction. That this is a reasonable attitude to adopt will, I think, be apparent when we consider the results of present inductive methods of cancer research.

### *Inductive Methods of Cancer Research.*

Search for the nature and cause of cancer has now been going on for well over 100 years. The first cancer research laboratory was established in London in 1802, and during the whole of the nineteenth century cancer was regarded as one of the great scientific problems which pressingly demanded solution. We have reached the poles, have solved the conundrum of flight, have discovered X rays and radium, the telegraph, telephone and wireless telegraphy. But while these and other difficulties of mechanics, exploration, physics, chemistry, transport have been born, have matured, have even become old and effete, that of cancer is still incubating. In our own line of work brilliant discoveries have been made in the domain of diseases due to microbial invasion; but cancer, which has received ten, twenty, even a hundred times more attention still defies all our efforts.

The history of cancer research is a record of gigantic labour, carried on by men of outstanding ability, at enormous expense to end in failure. We ask ourselves what are the causes of this want of success? Evidently it is not the result of any lack of effort or of competence. The more sure we are that the fault does not lie in this direction, the more likely is it that it is due to some mistake in our methods, some error of strategy? Let us now see in what this strategy consists.

At first cancer research was mainly *anatomical*. Cancers, both in the living and in the dead, were studied with great thoroughness, much to the improvement of classification, of diagnosis and of surgical treatment, but with very little result so far as an understanding of their nature and causes was concerned. A fresh impetus was given to this form of examination by the introduction of microscopy; but this extension of anatomy to the finer details of cancer structure, though carried to the point of exhaustion, has also turned out to be barren of the desired results. While searchers were still being exhorted to "think anatomically," fresh discoveries in bacteriology by Pasteur started a new and still more hopeful way of investigation. One after another disorders which had hitherto defied all attempts to understand them were now found to be due to invasions by minute forms of vegetable or animal life, and what could seem more likely than that cancer should be of the same category? But little, if any, progress having been made as the result of patient labour in this field of investigation, a third and still more hopeful way was opened by *biological* research. At the end of the last century the growth and behaviour of living cancers began to be studied in the bodies of lower animals. But, unfortunately, this new and encouraging departure is suffering from the prestige of morphology and bacteriology. As applied to cancer research biology is being mercilessly cramped by its association with these other two sciences in a sort of symbiotic trinity within the restricted and stuffy precincts of the laboratory. Nevertheless this third form of research, this offspring of the biologist and the bacteriologist, has already met with some success, though on a small scale, as befits its parentage. For whereas all the previous years of patient labour were barren as far as the main issue is concerned, out of the biological travail of this century has arisen a better knowledge of the living cancer as it occurs in rodents and fowls, and this seems a definite advance on the earlier knowledge of the forms and composition of dead cancers. Yet, as we look at the enormous growth of the cancer research movement and then at these results, we are inevitably reminded of the mountain in labour, for out of it has emerged a mouse bearing upon its back that strange burden, the neoplasm of Jensen. And it is upon this same mouse, this same *ridiculus mus*, that we are largely depending as the means by which the British lion is to be freed from the bonds of cancer.

However much this form of research may appeal to us, it is open to serious, even fatal, objections. If cancer is not the result of an invasion but is in truth a part of the animal it infests, it would evidently be very unsafe first to study the neoplasms of much lower forms of animal life and then to apply our inferences and theories to the neoplasms of human beings. By such study we may add to our knowledge of the growths of plants, of mice or of fowls, but not of men. It cannot too emphatically be asserted that, however ingenious the research made on these lines or shrewd the induction, no reliance can be placed upon it as an explanation of human cancer or of the causes of human cancer until it has been successfully applied to human beings.

The *conclusion* is that though greatly indebted to anatomy for our knowledge of the structure of cancer and for its bearings on treatment, it is of little use as a means of finding causes. Laboratory methods, again, though supremely useful in unravelling the tangled mysteries of the microbial disorders, are unfitted for cancer investigation. They are wrong in principle, seeing that there are cogent reasons for looking upon cancer as of internal origin and fundamentally different from the disorders due to microbial invasion.

### *Deductive Cancer Research: The Cartesian Method.*

We now turn to a form of deductive research advocated by Descartes some 300 years ago. As applied to the present problem it is based on the proposition that cancer of man is essentially an intrinsic disease, a piece of the man himself, and that for its solution we have all the data we require. According to this view the genesis of cancer is an affair of human genetics.

It was the opinion of Descartes that in the end all natural phenomena are mathematical and that provided the facts are sufficient and the laws understood it is possible by sheer calculation to solve any problem of nature or disease. It is in accordance with his system as described in his "Method of Rightly Conducting the Reason and Seeking Truth in the Sciences," that we need not wait until our knowledge of anything has become Euclidian before we begin our calculations. At no time is it more opportune than when a problem has resisted many years of inductive investigation and is buried under a vast mass of facts and theories. The method is, moreover, applicable to problems of disease. Descartes regarded it as eminently fitted for this purpose and thought there could be no higher task than to apply it to the advancement of medical research.

The Cartesian method was almost inevitably both analytic and synthetic, both destructive and constructive. Old, worn-out and dangerous methods and beliefs were of necessity broken down in order to make way for the foundations of a better structure. Its *destructive* or analytic effects were obvious. The wonderful advances in philosophy initiated by Plato and Aristotle which had done so much for the progress of knowledge and had inspired Galen had got into grooves. Science instead of going forward had lost its way and was moving in circles. Such non-progressive movements were not confined to theologists and philosophers, but flourished among the medical fraternity, who were entrenched behind centuries of tradition and were severely intolerant of those who would not adopt their own particular tread-mill methods of working.

It was one of the great merits of the Cartesian method that it tended to break down these time-honoured but costly and obstructive beliefs. Founded on doubt and with the single purpose of getting at the truth, it closely scrutinised even the most tenaciously held theories and practices. Authorities, vested interests, opinions, common beliefs were regarded as nought; nothing mattered except the truth. That a statement had behind it the weight of authority or of precedents was to Descartes the more reason for scepticism. By so winnowing the chaff from the wheat he did much to prepare the way for our present dependence upon rationalism and dislike of dogmatism; and also for the friendliness with which new ideas and new criticisms are now received even by conservative scientists.

So much for the *destructive* side of Cartesianism. The synthetic or *constructive* side was simplicity itself. In the investigation of any problem of natural science the Cartesian would study the laws and rules by which it is governed and regulated, comparing them with the facts and data. Though he proceeded mainly by deduction, his theories were never so much in advance of his facts as to lose sight of them, and sometimes it is a little difficult to say which were leading, the facts or the theories.

The method appeals not only by the force of its logic, but by its results, for it has often been applied with success. There can be no better example the successful use of the Cartesian method than discovery of the planet Neptune by A Leverrier. This represents the use of the its simplest form. So little had the telescope and sleepless nights of actual observation to do with this discovery that, according to Flammarion, Leverrier, 30 years afterwards, had not only never seen Neptune, but would not even trouble to put his eye to a telescope which was being directed to his planet. After the same fashion, to compare the very small with the very big, it is conceivable that an investigator working on the Cartesian plan might answer all the cardinal questions that may be asked about cancer without ever having seen a cancer. An inquiry into the causes and nature of cancer could be carried out by anyone who has the requisite data and sufficient acquaintance with the laws of life, especially with those which deal with origins and go by the name of genetics and with ecology or the science of relations. At the same time, so wide is the scope of such an inquiry that it will be to the advantage of the "researcher" that he should get all the information about the disease that he can. He should be familiar with cancers living in their natural surroundings, or, in other words, should himself be an operating surgeon. In addition, it will be so much the better if he has a private laboratory and the services of a competent assistant that he may know the structure of all sorts of cancers and precancers and allied diseases. To understand the wider aspects of the question at issue he should also have some knowledge of sociology. He should, in short, be a biologist in the largest sense of the word. Lastly, the "researcher," so equipped, and with all the resources of the best of museums and of medical libraries at his disposal, must be prepared to continue his inquiries until he has accomplished his task, although it may occupy his spare time for some 20 or more years.

### *The Results of a Deductive Cancer Research.*

The following is a brief account of some of the results of such a research, details of which have recently been published.[1] It would be impossible within the limits of this article to give even an outline of the many new interpretations of familiar facts of oncology which have thrust themselves forward and compelled attention. But two deserve special mention because of their importance and because they furnish excellent examples of the results of the method.

### *Nature of Cancer.*

1. The first interpretation is concerned with the great central problem of cancer—its ceaseless and useless proliferation. By the rational method of Descartes a simple and perfectly adequate answer is found already provided by biologists. Cancer as an intrinsic disorder has its source in the disturbance of some normal attribute of the body. By a process of analysis this is found to be *development.* Von Baer, Huxley, and Ray Lankester have shown that development is coterminous with life and has a progressive and a regressive or degenerative phase. There is first a rise from simplicity to complexity, then a fall from complexity to simplicity. Development, in other words, tends to assume a circular form. If we regard it from the standpoint of the individual it is circular; if from that of the race it is cyclical. In the latter event it marks a forward movement, fresh cycles being given off as the circle turns round. Modifications of this circle of development occur according to the unit of construction. Man as a whole, organs, cells, each has its own circle. The mechanism is one of lesser wheels and bigger wheels.

The development of *man,* as a whole, turns round in its course, so that in its regressive phase we can detect a debased repetition of the progressive phase. We all know the second childhood of man and some of us are familiar with his second infancy. Those who have carefully examined the tissues of old people also become acquainted with changes of an embryonoid character displayed more or less prominently in his various organs.

Then each *organ* lives its own life and provides its own circle, some circles being longer or bigger than others. These, too, begin in simplicity, become complex, and end in simplicity. Of the shorter or smaller circles the reproductive organs furnish the best known example.

Then come the *cells.* As a rule, the life-history of the cell is bound up with that of other cells in the organ to which they belong. But, as we all know, occasionally clusters of cells *qua* cells either fail to develop or run through their development too soon. Should they remain stagnant and unprogressive, one of several results may be expected: (1) The clump of cells will be absorbed. (2) It will resume its interrupted development and, if not too backward, will catch up with other cells to become a useful member of the cell community. (3) Or it will be so far behind as to remain permanently ill-developed and out of harmony with the surrounding cells. So truly may this be the case that to all intents it is a piece of tissue from an inferior animal. It will therefore be shut off or encysted. One of three things may happen to this incongruous patch: (*a*) it degenerates molecularly and is absorbed; (*b*) or it renews its progressive growth, but with a wrong chronology and with diminished restraint as a tumour; (*c*) or it enters upon its second childhood and then resumes an embryonoid character, proliferating after a debased fashion as a cancer. Cancers are, indeed, cells which have entered upon the degeneration of old age too soon and are being nourished by the juices and stimulated by the hormones of the younger, more vigorous tissues around them. They are often spoken of as embryonic, as if they were young cells. Cancer cells are not young or progressive, but are senile, regressive, decadent. They are embryonoid, not embryonic, and it is for this reason that they multiply so incessantly and so uselessly.

The importance of this cyclical theory of development in its bearings on pathology is difficult to exaggerate. With this in our minds we should be less inclined to confuse the granulomas or other progressive neoplasms of lower animals with the regressive neoplasms or cancers of man. The difficulties of distinguishing between progressive multiplication and regressive multiplication become greater as we descend in the scale of life, because the lower we go down the scale the smaller the developmental cycle; the more closely the embryonoid approximates to the embryonic. Indeed, in the case of certain neoplasms of plants the likeness to cancer cells may be so close that only the facts that these neoplasms favour young plants and that the plant has no true regressive phase comparable with that of a metazoan animal enable us to distinguish between them.

### *Causes of Cancer.*

2. The second outstanding feature of cancer is the manner in which cancers are brought into being. We all agree that the actual cause of cancer is to be traced to some outside source. This being the case, how can we reconcile this external cause with their internal status? By the Cartesian method we find the explanation in the action of *cancer-producing irritants.* The evidence is now overwhelming that for the production of cancer two factors are essential, the first factor being a passive predisposition possessed by some animals, men, organs, or cells to a higher degree than by others; the second factor a stimulant or irritant capable of rousing the cells into regressive activity. Translated into the language of biology these factors become "variability" on the one part and "suitable environment" on the other.

*The Irritant.*—It must now be our business to find how the passive predisposition or variability coöperates with the active irritant to start the cell multiplication which is cancer. Attention has often been called to the resemblance of the action of the irritant upon the susceptible cells to produce the proliferation of cancer, and the action of the male cell upon the female cell to produce the proliferation of the embryo.

---

[1] *Tumors and Cancers: A Biological Study.* By Hastings Gilford. 1925.

That this comparison is just, reasonable, and sagacious is shown by the presence of a series of connecting links between the two forms of neoplasms—the embryo and the embryonoid—and between the stimuli by which they are actuated.

(1) Thus in the beginning of the cycle of normal development the proliferating cells which constitute the embryo are the result of the action of three forms of stimuli There is first the mechanical stimulus of the entrance of the active spermatocyte; then the chemical stimulus of its molecular disintegration, and, most potent of all, a third stimulus, an actinic stimulus, liberated when the one cell acts upon or even approaches the other cell.

(2) But in this act of embryo formation the presence of the sperm cell is by no means essential; for, at any rate in the lower animals, a complete series of progressive developmental changes can be set going by artificial stimuli, by mechanical stimuli alone, by chemical stimuli alone, by actinic stimuli alone

(3) In the next place strong circumstantial evidence has been brought forward by competent observers tending to indicate that similar parthenogenesis sometimes occurs in human beings, resulting in the formation of imperfect embryos in the ovaries of women or even in the testes of men. Such embryomas lie in the border region between normal embryos and tumours.

(4) The next step is across this border The embryonic or undeveloped cells which constitute Cohnheim's cell rests in some ways resemble the reproductive cells in the ovary They are undeveloped, are clusters of cells set apart from the somatic cells in general, are more susceptible than *normal* cells to the action of mechanical, chemical, or actinic stimuli, and under the influence of such stimuli are capable of growing rapidly in a progressive if abnormal manner as tumours or regressively as cancers.

(5) The last stage of these gradations is reached when we come to those collections of primitive-looking cells which *form* pre-senile adenomas or papillomas, such as those which occur in the degenerating female breast. These are groups of cells which have *completed* their cycle of development before their time and have arrived at a stage of regressive simplicity comparable to that of the progressive simplicity from which they started. They have reverted to a form and function almost on a level with those of the amœba or of the oocyte; and, like all primitive cells, their faculty of reproduction stands out conspicuously as compared with other faculties. All that is necessary *for this reproduction* to assert itself is the action of an appropriate stimulus in an appropriate strength. Such a stimulus is supplied by trauma or other mechanical agent, by the toxins of some bacterial infection or other chemical agent, by X rays or other actinic agent.

Hence the self same forms of stimuli, which act at one end of the developmental cycle to start a proliferation of progressive type ending in the formation of the normal human embryo, are capable of acting at the other end of the cycle to produce the embryoma like proliferation of regressive type we term cancer Embryos are the tumours of the beginning of development cancers are the embryomas of the end of development

It is important to realise that though cancer is the parthenogenetic conception or offspring of aged tissues, it is the child of premature, not of *normal* senescence In normal senescence the changes of regression are accomplished so quietly, so unostentatiously, that nothing happens except the gradual substitution of a low order of (connective) tissue for a higher The weeds begin to flourish as the soil is exhausted and the crops fail But when local senility sets in before its time and the degenerated cells are aroused into reproductive activity by the violent and repeated action of some appropriate stimulus, it is but to be expected that the resultant growth will be regressive, *disorderly*, and excessive And once this embryonoid activity is set going, the comparative youth of the body at large will ensure that it does not fail from lack of support. Nutrients reach it through the blood and lymph streams as well as stimulants from the various endocrine organs. Hence the more youthful or sanguine or vigorous the body as a whole, the more malignant the cancer, and the more aged or shrivelled the body, the slower the growth of the cancer and the more likely to come to a stop

### *The Predispositions*

The active stimuli which incite to cancer are not to be compared in importance with the passive element which constitutes the predisposition to cancer These more subtle causes are intimately connected with the degenerative circumstances of our time. Cancer, as a degeneration, arising in circumstances of degeneration, *springs from causes so widespread that* we are able clearly to trace their influence in the changing customs of civilisation. Everything which promotes degeneration in general is potentially a predisponent to cancer If civilisation prolongs life into its senile states, it is a cause of cancer, if it keeps alive the inferior C3 quality of the nation and enables its degenerate members to grow up and multiply, it promotes mental and bodily *deterioration*, including cancer The study of the laws and regulations of biology has given us the assurance that in all living creatures in a state of nature there is a process of elimination at work by means of which the progressive qualities tend automatically to survive and the lower, baser qualities to succumb Cancer and other degenerative diseases are therefore scarce In wild life good ultimately rises to the *surface* and *bad* falls as a sediment to the bottom If we deliberately preserve the bad and cultivate a bad stock, while *we waste and discourage* and eliminate the good, using its superior qualities for the preservation and increase of the bad, we commit a mortal sin against nature by ensuring not the survival of the fit, but of *the unfit By this* means decadence prevails and an atmosphere is created congenial to mental and physical deterioration and to the various degenerative diseases.

Inadequate use of highly important organs, such as the reproductive organs *of women* or the digestive organs of both sexes, must also be regarded as a source of weakness and degeneracy and as rendering *those organs vulnerable* to cancer-producing agents.

### *Conclusions*

It is hoped that the rough and inadequate sketch which has now been given of some results of the Cartesian method of research as applied to cancer may convey some idea of its value and may induce others to pursue the same method of investigation. It will be seen that it *may correctly* be termed the method of the jig saw puzzle, for by it evidence is collected from all sources to be classified and arranged in accordance with *biological* laws Certain facts are correlated and made to dovetail in with other series of facts Gradually definite patterns begin to emerge out of the original chaos until at last the worker sees before him the whole picture clearly revealed

This solution, again, is not partial *nor indefinite*, but is a full and satisfactory reply to each and all of the six cardinal questions which must be answered before we can say we understand the nature and cause of anything In its complete form it tells us *when* cancer begins; *whence* or in what circumstances it arises, *where* it is placed These we know already, but by the Cartesian method we are enabled also to answer the far more important questions, *what cancer is*; *how* it begins; *why* we are afflicted with it. These answers, moreover, are not merely dialectical and superficial, each remaining in its *own pigeon hole* as a self-contained theory, but are interdependent, bound together in one fascia by the rational method of Descartes.

Cancer we see as a cluster of cells which, owing to over-stimulation and to more diffuse degenerating influences, are *finishing their* circle of development too soon Structure and function now approach their original simplicity and the faculty of reproduction, the most primitive of functions, released from all inhibitions, comes to the fore. Under the fertilising influence of one or more of the reproductive stimuli—actinic, chemic, mechanic—these cells burst forth into an embryonoid or amœboid reproductive activity and find their way along the lines of least resistance to all parts of the body.

# TUBERCULOUS ADENITIS TREATED BY RADIUM.

## A SERIES OF FIFTY CASES.

BY PHILIP GOSSE, M.D. DURH.,
ASSISTANT MEDICAL SUPERINTENDENT, RADIUM INSTITUTE, LONDON.

ALTHOUGH radium as a therapeutic agent is generally associated with the treatment of cancer, it can be of great use in the treatment of several forms of non-malignant disease. One of these—tuberculous disease of the lymphatic glands—responds very satisfactorily to irradiation with radium plates, and the following series of 50 cases treated at the Radium Institute, London, appears to be worthy of analysis and record.

From a study of the notes of these cases certain facts emerge. In many instances there was but little benefit noticed after the first application of radium, but definite improvement became apparent after the second. Various forms of screening and different lengths of application were tried in the early stages, but it was soon observed that the best effects were to be expected when the treatment was carried out in a long exposure with heavily screened apparatus, given during a 48 hours' stay as an in-patient, although good results were obtained when the patient was treated as an out-patient, with three or four daily sittings of six hours' each, making a total of 18 or 24 hours' exposure. If after a long exposure a second treatment were given, an interval of at least six weeks should be allowed to elapse between the two exposures to radium.

### *Selection of Cases and Diagnosis.*

The cases reported upon here were of all ages, from a few months to comparatively old age. The cases of children did best, but improvement is to be looked for at any age. Those patients who had received previous X ray treatment did not respond to radium so quickly as those who had not.

In most of these cases the question of the removal of the glands by operation had been discussed; and the various reasons for negativing surgical means were as follows: (1) The general physical condition of the patient. (2) Previous operation had been performed but disease had recurred. (3) The objection on the part of the patient, or the parents, to what they believe to be the danger of the operation, but much more commonly to the fear of disfiguring scars remaining in the child's neck afterwards. (4) In the more recent cases the doctor in charge of the case, having had good results in previous cases with radium, preferred to resort to that line of treatment from the first. (5) The operation for removal of tuberculous glands by surgery is now but seldom done.

Every doctor who has sent a case of tuberculous adenitis to be treated here has been written to, and asked for information as to the present condition of his patient, and whenever possible the patient has been re-examined at the Institute. In not a few of these cases which had been previously operated upon, besides the enlargement of the glands, disfigurement and even deformity were present, owing to keloidal changes in the scars. It is satisfactory to note that the same radium application given for the glands will at the same time reduce these keloid scars. When a patient comes for radium treatment, and on examination a swelling is found which contains fluid, this is first removed by aspiration. In those cases where there is a sinus leading down to one or more broken-down, discharging glands, treatment by radium is by no means contra-indicated. In fact, in most of the cases of this kind treated by radium the sinus has rapidly dried up and closed.

Although the diagnosis of tuberculous adenitis was made in a few cases from microscopical examination of gland tissue removed by operation, in most of them the diagnosis was arrived at by the clinical history and physical examination. It is to be noted that where a mass of glands diagnosed as tuberculous suddenly and almost completely disappears within a week or ten days of the first radium application, the case is probably not tuberculous, but proves later on to be lymphadenoma.

It is interesting in going over the notes of these cases to observe how on not a few occasions enlargement of the glands of the neck was first noticed some few weeks after the tonsils had been surgically removed. What the significance of this is, whether merely coincidence, or whether, owing to the removal of the tonsil, bovine tubercle bacilli have gained access through the bed of the tonsil, it is difficult to say, nor is it strictly concerned with the subject under discussion.

### *Technique and Results.*

The technique itself is simple. The glands to be treated, having been carefully located and palpated, are marked out on the overlying skin with a dermographic pencil. Over these localities "half-strength" plates—i.e., plates covered by 2·5 mg. radium element to each 1 sq. cm. surface, and covered by a sheet of Monel metal 0·3 mm. in thickness and screened with silver 1 mm. in thickness—are applied, and held in place by pieces of adhesive plaster. Over these a few turns of crepe bandage are placed. This causes no discomfort to the patient, but where the patient is remaining in the Institute for two days and two nights, the plates are removed occasionally for a few hours.

Of the cases of tuberculous adenitis treated at the Institute I have taken 50 consecutive ones, which show the following results: cured, 37; improved, 9; not improved, 3; dead, 1; total, 50; and these statistics give a very good idea of the results to be expected by treating with radium. The cases reported "cured" represent those in which the patient enjoys perfect health in every way, and has no glands that can be palpated, or at most merely small shotty hard bodies, consisting of fibroid tissue only.

Of the three cases which did not improve, in one the doctor in charge of the patient wrote to say that a week after the child returned to his home after radium treatment the glands swelled up and had to be operated upon, and a quantity of pus was evacuated. Another case, a male, aged 24, died of phthisis three years after the treatment. Such a rare termination of a case of tuberculous glands is worth while recording. In his letter the doctor stated that after the radium treatment the glands entirely disappeared and never returned.

### *Histology.*

The action of the radium on the tuberculous glands has kindly been described for this article by my colleague, Dr. J. C. Mottram, who writes as follows: "The cellular changes which follow the irradiation of tuberculous lymphatic glands finally result in fibrosis. There is an early disappearance of lymphocytes, which either disintegrate or are phagocytosed by macrophages. The lymphoid myeloblasts, except after large doses of radiation, do not perish, and later may re-form lymphocytes. The lymphoid follicles atrophy, only the central cells remain. The endothelial mesh-work of the gland remains little altered, except for a great increase of fibrous tissue, so that the whole gland, shrunken from the loss of lymphocytes and other cells, comes to consist of narrow spaces lined by endothelial cells running through thick fibrous tissue. In this tissue the tubercles persist, more especially the giant cells, and here tubercle bacilli have been found persisting many months after radiation. It has been concluded from these appearances that the good clinical results are due to the creation of a site unfavourable to the growth of the tubercle bacillus, rather than to any direct action of the radiation on the bacillus. The dose of radiation given is always very much less than the lethal dose for the bacillus; nevertheless, a direct action on the bacillus may also be a factor, for the reason that it is well known that sublethal doses of radiation effect a lowering of the virulence of bacilli."

I am indebted to the many medical practitioners who have written to me in reply to my inquiries about their cases treated at the Institute, and my thanks are also due to Mr. A. E. Hayward Pinch for much helpful advice.

## A CASE OF INTUSSUSCEPTION PRESENTING UNUSUAL FEATURES.

BY D. S. FAIRWEATHER, M.B., CH.B. EDIN.,

SENIOR HOUSE SURGEON, BLACKBURN AND EAST LANCASHIRE ROYAL INFIRMARY.

THE following case presents several features of interest.

H. W., a boy of 14, was taken ill suddenly on the morning of Nov. 28th, 1925, with collicky pain across the umbilical region. He vomited a little later, and before admission vomited everything he ate. On the 29th he had diarrhœa, which continued until admission. He stated that no blood was passed per rectum. The pain recurred spasmodically and seemed to spread all over the abdomen. He is said to have swallowed a pin two years ago. Previous health good. The patient has six brothers and two sisters, all healthy.

*Condition on Admission.*—He was admitted to the infirmary on Dec. 3rd; temperature 100° F., pulse-rate 110, respiration-rate 26. He did not complain of much pain, but looked ill. The abdomen was slightly distended, although there was no visible peristalsis. Generalised abdominal tenderness was present, which seemed more marked in the right iliac fossa. Rigidity was not marked, though definite resistance was made to palpation. A rectal examination was made and a mass situated in the pelvis palpated. The mass seemed to lie slightly more to the left and was very tender. There was no blood on the palpating finger. A diagnosis of abscess from a pelvic appendicitis was made and an operation performed immediately.

*Operation.*—A right paramedial incision was made. Coils of small intestine were found to be distended, and a mass lying in the pelvis was brought to the operation wound. It was an intussusception involving about 18 inches of small intestine. Attempt at reduction was immediately followed by splitting of the serous coat of bowel and very little of the intestine could be freed. The affected loop was therefore excised and a lateral anastomosis performed. A small drain was inserted as there had been some slight leakage of intestinal contents and the abdomen was closed.

*Pathology.*—The specimen was examined subsequently and the entering and receiving loops found to be gangrenous in places. No pathological condition could be found to account for the production of the intussusception, although no definite attempt was made to find whether the swallowed pin could have accounted for the condition, as this fact was not disclosed until three weeks afterwards.

*Progress and After-treatment.*—The patient was given frequent salines subcutaneously, and on the second day following the operation the drain was removed, a little blood-stained discharge persisting for two or three days. His temperature reached 101·2° on the second day after operation, but soon dropped to 99°, and did not again rise. The bowels moved twice on the fourth day after operation without aperient, and have done so normally since. He was discharged on Jan. 4th, 1926, in perfect health.

Unusual features in the case are: (1) the age of the patient; (2) the alleged absence of blood in the fæces; (3) the rather unusual site of the intussusception; (4) the almost uneventful recovery after such an extensive operation and on a patient who had suffered five days before operation.

My thanks are due to Dr. W. Cran Duthie, honorary surgeon to the Blackburn Royal Infirmary, for permission to publish this case.

## SKIN-GRAFTING IN ACUTE SYMBLEPHARON.

BY JAMES MOORES BALL, M.D. UNIV. OF IOWA,

MEMBER OF THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THE writer is not aware that the method described in this paper has been used previously in the treatment of acute symblepharon; yet, it would be most strange if it had not been employed. In the hope that this note will elicit information on the subject, it is put on record.

Extensive burns by lime rarely come under my observation. A few months ago, however, a young man was brought to me, who, five days previously, had had both eyes sprayed with lime, cement, and débris from a hose, into one end of which he had looked, and which he was about to use in washing his automobile. Unknown to him, the hose had been used by men working with lime and gravel.

The right eye presented numerous adhesions between the eyelids and the eyeball. Fortunately, the cornea was clear, and daily separation of the involved structures has left an eye with vision better than 20/16.

The left eye was very different. Here were extensive adhesions, and a cornea so thoroughly cooked that it resembled porcelain. What was to be done in the attempt to save a sightless globe with normal movements? Evidently the logical procedure would be to separate the adhesions and prevent their re-formation by means of Thiersch grafts. Under general anæsthesia adhesions were severed, dissection was carried to and slightly beyond the extent of the normal fornices, and re-attachment was prevented by anchoring grafts between the eyelids and the eyeball. A huge graft was sewed into the upper fornix. The lower fornix presented a more difficult problem. Here a silver plate (provided with several openings at each end), of the approximate length and depth of the inner surface of the lower lid, was used. A large graft was spread over and was sewed to the plate. The plate, thus covered, was then placed with its lower edge about 2 mm. below the lower boundary of the fornix, and was anchored to the eyelid.

The end justified the means so far as concerns the separation of the lids from the globe. In a short time the globe became soft and distorted, and showed signs of impending perforation of the cornea. At the end of four weeks the eyeball was enucleated. The attempt to save the globe was a failure; but, on the other hand, the patient has an ample space for a prosthesis. He wears a too-large eye at night, to prevent contraction of the tissues; and a smaller, cosmetic, one by day.

St. Louis, Missouri.

---

PROGRESS OF SHROPSHIRE HOSPITAL.—Extensions now being carried out at the Eye, Ear and Throat Hospital for Shropshire and Wales include a new out-patient department and a new ward and dormitories for the nurses and staff. In response to a call for 1,000,000 shillings £10,000 have already been received, and of this the hospital's share is £7050. During 1925 4463 patients were treated, and still there is a waiting-list of 200.

# Medical Societies.

## MANCHESTER MEDICAL SOCIETY.

AT a meeting of this Society held on March 31st Prof. A. H. BURGESS, the President, took the chair, and Dr. T. A. GOODFELLOW opened a discussion on

### *Rickets.*

The discovery of the accessory food factors by Gowland Hopkins in 1912 was, he said, the starting point of the intensive research of recent years. Various ætiological theories had been from time to time suggested. At present these were concerned chiefly with hygienic causes and dietetic causes; the importance of the former was stressed by the Glasgow School and this view claimed support from the work of Margaret Ferguson under the Medical Research Council. The more recent work—especially that of the Mellanby's, of the British research workers in Vienna, published in 1923, and of many observers who had been noting the effects of the ultra-violet rays upon animals and foodstuffs as well as on rickety children—has considerably narrowed the field for discussion. The majority of observers now agreed with Mellanby that the three essential factors in the ætiology of the disease were: (1) an organic factor in the diet which is concerned in the calcification of bone; (2) light, either direct sunlight or radiations from the mercury-vapour quartz lamp; (3) an adequate amount and correct balance in the diet of the salts of calcium and phosphorus.

Dr. CATHERINE CHISHOLM dealt with the manifestation of rickets in the first two years of child life. She drew attention to the frequency with which child after child in one family contracted rickets, the incidence being out of all proportion to that of a family of neighbours living under similar conditions. Attention should therefore be paid to familial tendency. Personal idiosyncrasy, as shown by one twin taking rickets when housed and fed like its brother, has also to be considered as a factor. The weaning time of 200 cases of rickets entering hospital at varying ages showed a predominately large number of cases weaned in the first two months. Investigations were made on 75 children in Manchester and it was found that of these infants a certain number were weaned before the age of two months. Seventy-five per cent. of these early-weaned cases developed rickets, though the incidence of rickets in the 75 children under observation was 26·6 per cent.

Whether rickets was primarily (*a*) a disease of bone, or (*b*) the defect was merely one symptom of an entity, rickets, or (*c*) the rickety condition was merely a symptom or sequela of wasting diseases, at all events, said Dr. Chisholm, the bone change was the main feature of the condition found. A combined radiological and clinical examination was therefore necessary in diagnosis. The classical clinical symptoms alone could not be depended on. Two types of rickets were well described by Wimberger. Clinically, it was easy to under-estimate the amount of bone change in mild cases of the first or florid type, and radiologically in the second or passive type. As to the general incidence of rickets in the population, Thomson, of Edinburgh, stated that between 1895–1900 over 50 per cent. of the children under 3 years of age attending the Hospital for Sick Children showed unmistakable signs. Dr. D. H. Paterson had found 1·2 per cent. of active rickets in London in April, 1925; 32 per cent. had had rickets. Dr. Helen Mackay, in a different investigation, had found at least 8 per cent., but nearly all of them were slight cases. In an examination of 75 cases of unselected Manchester children who had never attended infant welfare centres, 26 per cent. of active rickets was found, of which two-thirds were well-marked cases. At least 46 per cent. radiologically showed suspicion of having had rickets. Of Dr. Paterson's London cases 92 per cent. were taking oil regularly. Of the Manchester district cases only five children—i.e., 6 per cent.—were having oil.

The treatment of rickets was obviously to supply the chemical constituents needed, in the form, or with the medium, which helped in their absorption, and under conditions which used them to the best advantage. Various attempts had been made to irradiate food lacking in vitamins or to isolate the vitamin factor and add to the diet. At the Babies' Hospital infants had been radiologically examined and watched on different lines of treatment. Unfortunately, it was impossible to deal with infants as laboratory animals, and intercurrent troubles were always arising to confuse the experiments. But the apparent results at present were:—

1. With a well-balanced diet alone, rickets may be healed even when advanced; but this takes a long time, during which the infant must be given exercise, but prevented from putting weight on his weak limbs. The healing is irregular as well as slow and shows relapses.

2. Massage in addition is not of much value in the actual healing of rickets where bone lesions are marked. The muscles may improve, the child may learn to walk, and progress may apparently be satisfactory, but the bones only heal slowly.

3. Cod-liver oil is the most dependable single agent for cure and in combination with Parrish's food is a reliable mode of regularly healing rickets.

4. Mercury-vapour light certainly helps to cure, particularly in the lethargic type with flabby musculature or the small atrophic type. Both types of infant seem to be stimulated by the rays and respond well.

The use of cod-liver oil with ultra-violet rays, said Dr. Chisholm, was an excellent and quick combination. A combination of food, massage, light, and oil certainly produced the quickest and best results in the cases selected in the autumn of 1925. Best of all, however, was cod-liver oil and natural sunlight, even in Manchester, when the summer was good, and when the infants were properly fed and clothed, and exposed under suitable conditions.

Mr. HARRY PLATT said that to the surgical mind rickets essentially presented a problem in the prevention and cure of deformity. Many of the efficient measures used to-day in the treatment of rickety deformities had undergone little modification since their introduction many years ago. At the present time operative intervention in rickets was being placed on a sounder basis. A deformity corrected in the stage of florid rickets was always likely to recur, so that some criterion of the activity of the disease was needed. This had now been provided as a result of a study of radiograms of the epiphyses in the various stages. In the infant the radiological index of activity had been completely established, but it was not so definite in the older child or adolescent. A more careful clinical examination of patients presenting the syndrome of late rickets had revealed the occasional occurrence of so-called renal rickets, in which the operative correction of deformities was always followed by disaster. Such experience emphasised the importance of a careful examination of the urine, and an estimation of the kidney function.

Rachitic deformities which called for the attention of the surgeon usually affected the lower limbs, and of these there were three main types—bow-legs, knock-knee, and coxa vara.

*Bow-legs* was essentially a deformity which showed a tendency to spontaneous rectification and it was rarely necessary to employ any special measures, and still less necessary to operate. For the extreme degrees of deformity in older children, tibial, or more rarely, femoral osteotomy was occasionally needed. Manual osteoclasis was possible when the bones were soft, but at this stage spontaneous cure could be expected in the majority of cases. Anterior bowing of the tibia was a deformity often best left alone. Its correction by operation in the extreme cases was not easy.

*Knock-knee*, in contra-distinction to bow-legs, was usually a progressive deformity and, once initiated, tended to increase long after rickets had healed. As it was determined chiefly by weight bearing, in the early stage this should be prohibited wherever possible. Under the exceptional conditions of an open-air hospital, moderate degrees of rachitic knock-knee would disappear without any form of splinting. In ordinary hospital out-patient practice it was usual to apply a corrective walking appliance, the best form being the classical knock-knee brace of Thomas. A great many cases of knock-knee in older children, however, came for operative correction, and on the whole the results of femoral osteotomy were exceedingly good, provided the after-treatment was adequate. In younger patients, after femoral osteotomy, the limb could be treated by immediate fixation in a plaster-of-Paris spica. In the adolescent and young adult it was desirable, however, to employ traction on a Thomas splint for as long a period as possible. This minimised the angulation and overlapping of the fragments and helped to ensure rapid union. Re-fracture after a femoral osteotomy was not an uncommon experience. In the older patients it was sometimes difficult to reproduce the full mobility of the knee-joint in a short time.

*Rachitic coxa vara* could be almost ignored, as it was chiefly a deformity appreciable only in radiograms. It had long been recognised that it invariably underwent spontaneous cure. Deformities of the upper limb possessed little surgical interest. Deformities of the chest were important, and once fully developed could rarely be corrected, although general benefit was gained from regular gymnastic exercises. In the production of spinal deformities rickets was a subsidiary or negligible factor.

Dr. G. V. Ashcroft read a paper on

### *Renal Rickets*,

in which he presented the results of an inquiry made at Ancoats Hospital into the association of rickets with renal disease. One typical case was described in detail with results of urea tests. In renal rickets, he said, the clinical picture was one of the onset at puberty of deformities of the late rickets type, associated with a profound muscular asthenia, pallor, stunting without infantilism, urine of low specific gravity, pale in colour and containing albumin, a notable absence of œdema and cardiovascular change, a negative Wassermann, a negative Loewi, and a negative Goetsch test. The X ray picture was one of rarefaction and metaphysical abnormality, hazy porosis, enlargement and lack of cortex, associated with some rachitic changes at the epiphysial line. Post-mortem examination showed chronic interstitial nephritis associated with fibrosis of the suprarenal gland and an inactive thyroid gland. The degree of renal involvement was roughly parallel to the degree of clinical and X ray abnormality. It was to the association of the typical clinical picture, the typical X ray picture, and deficient renal function that the term renal rickets had been applied. Dr. Ashcroft laid emphasis on the risk of uræmia following operation and the poor result obtained by osteotomy in such cases. In view of the frequency of the condition and the ease with which it might be overlooked, it was suggested that before an adolescent with bone deformity came to operation renal function tests should be carried out. Of the 24 adolescents with rickets investigated, 33 per cent. revealed definite renal inefficiency and 51 per cent. revealed some renal defect. Sufficient evidence had been found to warrant the suggestion that while the kidney lesion was responsible for certain of the findings, such as albuminuria and death from uræmia, the greater part of the condition might be due to fibrosis of the suprarenal gland.

## LIVERPOOL MEDICAL INSTITUTION.

At a pathological meeting held on March 25th Dr. J. C. M. Given, the President, took the chair, and Mr. D. R. Owen read a paper on

### *Acute Phlegmonous Gastritis*

in which he described two cases recently seen at the David Lewis Northern Hospital within a few weeks of each other.

1. A female, aged 60, who gave a long history of indigestion, was admitted and operated upon for perforated ulcer. The true condition was diagnosed at operation, and an anterior gastro-enterostomy was performed with a view to draining the stomach; abdominal drainage was also provided. She died, and the diagnosis was confirmed at the autopsy 24 hours after operation.

2. A man, sent in with the diagnosis of perforated ulcer, was operated on as an "acute abdomen," the signs not being typical of perforation. The condition was recognised at operation, and as there was pus in the pelvis all that was done was to place a drainage-tube in the recto-vesical pouch. The abdomen was then closed.

At autopsy a similar condition was found in each case. The stomach was greatly thickened and showed signs of acute inflammation; its cut walls oozed pus. There was an acute cellulitis of the stomach in each case, although there was no sign of recent ulceration, and no cause of the cellulitis was found. In the first case bacteriological examination was not made, but in the second a mixed infection of *B. coli* and streptococci was found.

One point which Mr. Owen wished to bring out, he said, was the presence in these cases of a stomach dullness area, not previously described, such as might be expected considering the pathological findings.

After describing the recognised localised and diffuse types of the disease and showing that his cases belonged to the latter—the so-called idiopathic or primary phlegmon of the stomach—he suggested that some of Alexis Thomson's cases of fibromatosis of the stomach might have been cases of cured phlegmon of the stomach. The ideal treatment, he said, was gastrectomy, but at the time when they were seen these patients would not stand such an operation. He therefore advocated the application of general surgical principles, when the condition was recognised after mid-line or right abdominal section, which would be the usual operation performed. The two essentials were to feed the patient and to deal with a cellulitis. He was therefore in favour of a jejunostomy through a new incision to the left—in order to feed the patient and to relieve any distension which might occur—then opening the stomach and incising its thick walls to let out the pus. Before opening the stomach it should be fixed to the abdominal wall to prevent infection of the peritoneal cavity. In this situation it could be treated as any other cellulitis would be treated. If serious hæmorrhage were feared the main vessels of the stomach could be secured before making incisions into its walls. In favour of this he argued that further operation would almost certainly be necessary if the patient recovered for removal of adhesions or of a fibrotic stomach, and therefore the cutting off of the gastric blood-supply would not be of great danger. As in the past, only one or two cases had been known to recover; he thought that new, even if heroic, measures were needed.

## NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

At a meeting of this Society held on March 31st Mr. H. Bell Tawse, the President, took the chair, and Mr. Victor Bonney read a paper on the

### *Causes of Sterility and their Treatment.*

Speaking of sterility generally, he said, there were certain factors which could not be accurately assessed and certain others which could. Prof. Arthur Robinson had shown that in animals—and probably also in human beings—there was a wastage of 40 or 50 per cent. of the ova shed by the ovary in circumstances favourable for fertilisation. This wastage was brought about in several ways. Some ova never reached the tubes, but were lost in the peritoneal cavity; others, though they reached the tubes, did not blend with a sperm, though sperms were there; others again, though blending with the sperm, perished within a few days of the union, apparently owing to an inherent deficiency of vitality. There were at present no means of diagnosing such happenings in the case of a sterile woman, nor indeed of being sure whether she ever passed fertilisable egg-cells out of her ovary. The factors which could be assessed were the patency of the genital canal from top to bottom, the healthiness of the sperm, its deposition in the vagina, and its ascent therefrom. Patency of the female genital canal was essential, and the recent introduction of tubal inflation had greatly extended our diagnostic capabilities in this respect. Every woman examined under an anæsthetic to find the cause of her sterility should have her tubes inflated, and if they were found blocked the best course in most cases was to open the abdomen at once and attempt to overcome the obstruction. The attempt was often successful, the most favourable cases being those in which the abdominal ostia alone were closed as the result of pre-existent inflammation. Absolute blockage in the uterine and vaginal segments of the canal was rare, but stenoses were not uncommon in the cervix and at the vaginal orifice; good results often followed operative dilatation of the cervix.

The upper two segments of the genital canal, said Mr. Bonney, were the follicle itself and the space between it and the abdominal ostium, this latter being the peritoneal segment of the canal. Obstructions could occur from non-dehiscence of the follicle or from the intervention of omental or other adhesions in the peritoneal segment. Non-dehiscence of the follicle did not lend itself to treatment, but obstruction between the follicle and the abdominal ostium might be cleared away. Much could be done by conservative surgery on the uterus, the tubes, and the ovaries to preserve the existing chances of pregnancy or to make pregnancy possible when hitherto it had been impossible. Emphasising the propriety of examining the man as well as the woman, Mr. Bonney spoke of the phenomenon of profluvium seminis and of the possibility of the sperms being killed by the vaginal discharge. Nothing much of scientific value was known about this last; the subject needed investigation, but it was difficult to get anyone to undertake it. As regards artificial insemination, his own experience had been uniformly disappointing, but where, on account of physical deformity, the sperm could not be deposited in the upper vagina it was the logical treatment.

The address was discussed by the PRESIDENT, Dr. J. C. BUCKLEY, Dr. G. E. J. A. ROBINSON, Dr. J. WATSON, Dr. W. R. SMITH, Dr. C. D. LOCHRANE, and Dr. C. H. ALLEN.

# Reviews and Notices of Books.

## STATISTICAL METHODS.

*Statistical Methods for Research Workers.* By R. A. FISHER, M.A., Fellow of Gonville and Caius College, Cambridge; Chief Statistician, Rothamsted Experiment Station. Biological Monographs and Manuals. No. III. General Editors: F. A. E. CREW, Edinburgh; D. WARD CUTLER, Rothamsted. Edinburgh: Oliver and Boyd. 1925. Pp. 239. 15*s.*

THE ideal position for a research worker to aim at is to be as independent as possible of statistical methods—to be able, that is, so to arrange his experiments as to allow one condition, and one only, to vary at a time, and thus to get a direct answer to a direct question, unclouded by the variation of disturbing factors irrelevant to the point at issue. In no field of research are workers wholly in this happy case—least of all in medical science. This is obvious enough in its final application, dealing as it does with man himself with whom experiment is clearly restricted. Here to a large extent the observational method must be used, disturbing conditions are partly out of control, it is not always possible to repeat an experience, and at times the whole staging of the experiment is, perforce, in the hands of Nature. Between pure observation and the ideal experiment lies a very wide field of research work which is more or less closely dependent on accurate statistical treatment as it approaches one limit or the other. Prof. Topley's recent Milroy lectures, lately reproduced in these pages, illustrate one branch of medical research—that of epidemiology—in which even in its experimental form the methods of the statistician are indispensable.

The research worker who is led by the title of Mr. Fisher's monograph to expect a comprehensive survey of statistical methods will be demanding more from the book than it offers. The clue to its content is found in the editors' preface, which states that one of the objects of this series is to give those who have contributed notably to the development of a particular field of inquiry the opportunity of presenting the results of their researches in a more extended form. This work deals chiefly with the large number of statistical problems which confront the laboratory worker who is obliged to deal with comparatively small samples. It is described by the author as an elementary book, is without mathematical proofs, and is designed for readers without special mathematical training; thus it is out of the ordinary run of statistical text-books—above them in many respects, in others below them. It is above them in so far as Mr. Fisher is an expert and original mathematical statistician, and the book is based largely on his own work in adapting suitable methods to the practical problems in view. The methods explained are illustrated by numerical examples, well chosen as typical of those which continually arise in practice. The numerical tables given are put in a simple form for practical use, so that tests can be made without the evaluation of complicated algebraic expressions. The faults of the book are such as arise from Mr. Fisher's talents. He has not always wholly succeeded in putting himself in the place of his less accomplished reader and realising his difficulties, though on the whole this work shows in that respect a great advance from the somewhat obscure style in which Mr. Fisher's purely mathematical works are written. No indication is given to the beginner as to which of the methods described are generally accepted, and which are based on convictions which are still a matter of controversy between Mr. Fisher and other statisticians of equal eminence. A certain lack of historical sense is shown by the rather inadequate acknowledgment of the work done by earlier writers. Perhaps Mr. Fisher owes more than he realises to the "traditional machinery of statistical processes" of which he speaks so scornfully, and not least to the extension of that machinery by Prof. Karl Pearson. One or two minor defects may be noted. The first example, which is designed to illustrate a method of calculation, is obscured by the introduction of technical terms which will be unfamiliar to many readers. It is definitely outside the scope of the work to give proofs of the methods described, but references in the text to the bibliography would help many who are not content to take everything on trust, and wish to know where the proofs may be found.

The ground covered is well suited to the needs of the practical worker. The introduction contrasts the aims of modern statisticians and those of their predecessors. The older workers were chiefly concerned with average or aggregate values, while "from the modern point of view the study of the causes of variation of any variable phenomenon, from the yield of wheat to the intellect of man, should be begun by the examination and measurement of the variation which presents itself." This leads at once to the idea of a frequency distribution, and to that of a hypothetical population of which the data observed may be considered as a sample. The behaviour of the different "constants" or typical values chosen to describe a population, when random samples are taken, is the basis of the tests of significance by which we can examine whether or not the data are in harmony with any suggested hypothesis. If, for instance, we wish to compare the rates of growth of two parallel cultures of an alga, we shall not be able to decide if the difference is definite enough to assert that culture B was growing more rapidly than culture A, unless we know what sort of chance variations in the rates are to be expected in samples of that size in which no real difference exists. The three most important distributions—the normal, the binomial, and the Poisson—are clearly described and illustrated, and also the manifold uses of Pearson's "Goodness of Fit" test of the agreement between observation and hypothesis.

"Student" gave in 1908[1] tables which made it possible to test whether the observed mean of a small sample differed from any theoretical mean to a greater degree than was likely to arise by pure chance. Mr. Fisher gives these tables in a simplified form, and also shows how to use them for the even more frequently recurring problem whether the difference between two observed means of small samples is large enough to justify the assumption of a real difference between the samples. From the significance of means we are led on to the idea of "regression"—i.e., to the expression of the average value of any variable in terms of the values of one or more other variables—e.g., the average yield of a cereal for given values of rainfall and temperature during the preceding year. The treatment of the correlation coefficient—a measure of the degree in which two quantities increase or decrease together—is clear, but Mr. Fisher seems to do less than justice to the more complete measure of association, the correlation ratio. Tables are given to test the significance of differences in correlations found from small samples, and to combine a number of independent estimates into an improved estimate by means of a transformation, suggested by the author, which leads to a simpler distribution of sampling errors than that of the correlation coefficient itself. The final chapters on intra-class correlation and the analysis of "variance" will not be found easy by the beginner, but will repay careful study on the part of the student with experience, and will help him to grasp the analogy between evaluating the correlation between members of the same class (say correlation in yield of potatoes grown on the same patch), and the estimation of the relative importance of different groups of factors causing variation. The book contains much that is of value, and will be useful both for reference in practical work and as a summary of the treatment of small sample problems. The average beginner in statistical methods will, however, find himself at times in rough seas if he tackles it alone as his first introduction to statistics.

## TUBERCULOSIS.

*Die Lungentuberkulose.* Third edition. By Dr. FELIX KLEMPERER. Berlin and Vienna: Urban and Schwarzenberg. 1925. Pp. 289. M.10.80.

Dr. Klemperer's text-book has evidently found a place in German medical literature, for this is the third edition to appear since 1920. The book is well-balanced and gives a proportioned survey of the subject, from the historical introduction to an appendix on climate in tuberculosis. In the chapter on pathological anatomy the writer uses the nomenclature of exudative and productive tuberculosis, introduced by Aschoff, which in continental writings of recent years seems to have replaced the older nomenclatures of tuberculosis. Gräff and Küpferle's classification of primary, bronchogenic, and hæmatogenous is also given. The use in addition of the terms "primary," "secondary," and "tertiary tuberculosis," on the analogy of syphilis, appears to us to confuse rather than to help. In the brief section on statistics, figures are given showing the influence of the social factor in tuberculosis; here the death-rate is arranged for families with different incomes, whilst a subsequent table shows the influence of the housing problem by tabulating the death-rate according to the number of rooms per family. The table giving comparative mortality-rates for the different European countries is meagre and incomplete. In the chapters on diagnosis, modern serum diagnosis and X ray examination receive due consideration, and in chemotherapy the heavy metals and other modern drugs are discussed, as well as the recent work on sanocrysin. Treatment with tuberculin is dealt with at considerable length, Friedmann and Ponndorf's methods receiving an unusually large amount of attention. The Deycke-Much antigens are also described in detail. These various active immunisation methods evidently continue to play a larger part in the treatment of tuberculosis in Germany than they do in this country. Artificial pneumothorax technique and surgery of the chest are also discussed, but these important sections appear to us to be summarised rather too briefly in comparison with the greater detail given to specific inoculation treatment. A bibliography chiefly confined to German works is excellent as far as it goes. The book contains numerous illustrations of value, and is a sound work eminently suitable for the general practitioner and the post-graduate student.

## ESSENTIALS OF PSYCHIATRY.

By GEORGE HENRY, M.D., Senior Physician, Bloomingdale Hospital. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1925. Pp. 199. 13*s.* 9*d.*

UNTIL the pathological bases of mental disorder are properly established, it is fairly sure that there will not be a really good book in psychiatry. At present psychiatry is too elusive and too wide a subject to lend itself to text-book treatment, and the only chance for an author to achieve some measure of success is to decide beforehand exactly what aspect he is going to stress and to which public he is going to appeal, and then to keep this object relentlessly before his eyes. For instance, he may deal with insanity as it appears to the clinician, the biochemist, the psychologist, the nurse, the social worker, or the advocate of religion, and, if he endures to the end, he has a good chance of teaching his limited public quite a lot that they did not know before. He may, if he wishes, include all that the pathologists have discovered up to date about insanity; it will not appreciably distend his book, and so far from confusing the issue will clear up several points which would otherwise remain obscure. But if he once falters and hopes to compromise between more than two at most of these points of view he is lost.

This is the rock upon which Dr. Henry has floundered. It is obvious that he has been powerfully attracted by the claims of the social worker to psychiatric knowledge, and very rightly. There is a crying need among voluntary helpers for a sound, intelligible, popular work on mental disease. But, having this desire, he should have followed it instead of attempting to give his book a veneer of clinical respectability at the same time. The result has been a splitting-up of his personality into five or six portions, of which not one possesses enough of the original interest-flow to make it worth while in itself. He has dealt with the clinical aspect, but so superficially and flittingly that the clinician will turn away empty. He has pronounced leanings towards Freudian psychology, but he never develops fully its implications in the subjective life of any one case. He has a chapter on insanity and law, where he indicates a few details on certification and responsibility, and adds a good chapter on nursing, written by Miss Adèle Poston. There is hardly a word on pathology or morbid anatomy, and not a single reference to another book. He only obtains relief from the abstract and passive kind of attitude which obscures the clinical part of his book when he is writing frankly for laymen about evolution, psychiatry for the social worker, mental hygiene, and the number of great men who have had something wrong with their minds. This section is of its kind excellent, and the author would be well advised to go further and produce a book for the social worker written, like this one, "in language which is within the range of familiarity to the general public," but free from a dead weight of unhappily-presented clinical material. The present work cannot be of use to the professional psychiatrist, and is too cumbersome for the amateur. It is, nevertheless, an attempt at a difficult task, and Dr. Henry deserves credit for it. He is obviously enthusiastic enough about his subject to try to do better next time.

VETERINARY POSOLOGY.

*Table of Veterinary Posology.* And Other Information for the Use of Students and Practitioners. Fifth edition. By G. A. BANHAM, F.R.C.V.S., and WM. J. YOUNG, F.R.C.V.S., D.V.S.M. London: Baillière, Tindall and Cox. *1926. Pp. 359.* 8s. 6*d*.

IN the preparation of the fifth edition of this book the authors have had material help from Mr. A. W. Noel Pillers, Mr. H. Gray, Mr. J. S. Lloyd, Sir John McFadyean, and Prof. F. T. G. Hobday. The manual has been increased in size by 100 pages, and in these useful information is given on the identification of parasites, and the Animals (Anæsthetics) and Horse-Breeding Acts. The Dictionary of Synonyms and Trade Names for Drugs is a long and comprehensive one, but it is by no means exact and needs some revision. For example, *oleum kervinum* and *oleum menthæ* are not trade names for castor oil and oil of spearmint respectively. The posological section of the work is well up to date, but we notice omissions of all the salts of silver in the *collyria*. As an animal product of wide application insulin might deserve mention.

The book is well known to all veterinary students and practitioners, and each successive edition has been an improvement and advance on its predecessor. We hope that no further increase in size will be made, since the work is designed for handy and quick reference.

CHRONIC PANCREATITIS WITH JAUNDICE.

*Pancréatites Chroniques avec Ictère. Causes, Diagnostic et Traitement. Valeur et Résultats Éloignés de la Cholécystogastrostomie.* By Dr. PIERRE MALLET-GUY, Interne lauréat des Hôpitaux de Lyon, Aide d'Anatomie. Paris: Masson et Cie. 1925. Pp. 307. Fr.25.

Dr. Mallet-Guy has collected a series of interesting observations concerning those rare cases of jaundice due to chronic inflammatory lesions of the pancreas, with special attention to the results of cholecystotomy and cholecystenterostomy for the relief of this condition. The diagnosis between such lesions and those due to slow-growing cancers of the head of the pancreas or of the papilla of Vater is practically impossible and can, as the author rightly points out, only be determined by the clinical evidence of recovery and survival after the operation. Even in malignant cases there is usually considerable immediate improvement, and it is only the existence of good health 18 months or more after the operation that justifies a diagnosis of chronic pancreatitis as the original lesion. Altogether a useful little book.

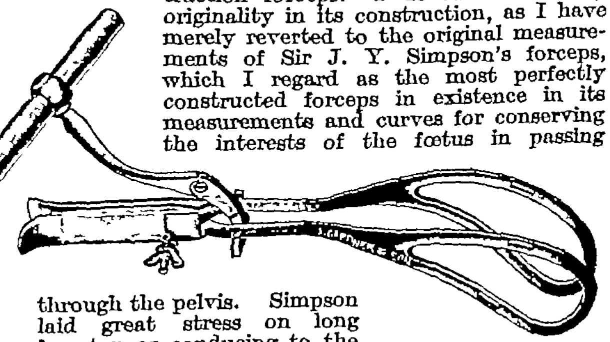
## AXIS-TRACTION FORCEPS.

THE midwifery forceps here illustrated is a modified *axis-traction instrument* which I devised 16 years ago and have used ever since with satisfaction. By its use I have reduced my fœtal mortality in difficult cases by about 10 per cent., as compared with my previous results in similar cases with the ordinary rod axis-traction forceps. I do not claim any originality in its construction, as I have merely reverted to the original measurements of Sir J. Y. Simpson's forceps, which I regard as the most perfectly constructed forceps in existence in its measurements and curves for conserving the interests of the fœtus in passing through the pelvis. Simpson laid great stress on long fenestræ as conducing to the safety of the child, and my experience fully bears out his contention. In the attempt to obtain *axis-traction* with traction rods the fenestræ have been shortened by half-an-inch in order to secure *the attachment* of the rods as high as possible, and even then real axis-traction at the upper *strait* is *not* secured, as I have demonstrated in my paper on the subject read to the Edinburgh *Obstetrical* Society in February of this year. In this forceps I aim at getting axis-traction without shortening the fenestræ. Traction with the traction handle secures sufficient axis-traction in *the cavity* and at the outlet in the ordinary average forceps case, and in the rare cases where axis-traction at the brim may be deemed necessary this can be secured *by tape traction through the eyelet holes in* the blades at the middle of the fenestræ. This tape *traction (as advocated by Fabre) secures* more adequate axis-traction at the brim than is possible with rods.



The measurements of this forceps from the Smellie lock upwards conform exactly to Sir J. Y. Simpson's measurements. I have shortened the handles for three reasons: (1) to indicate that they are not meant for traction; (2) to discourage the use of the handles for application (believing as I do that the blades should be applied by the shanks as tending to ensure their more gentle introduction by delicate manipulation); and (3) to allow the traction handle to work free from obstruction by the forceps handle without making the attachment of an inordinate length. The screw is the same as in the ordinary rod axis-traction forceps. Its use can often be to a great extent dispensed with, as the simple device which attaches the traction handle serves for all practical purposes to make the screw unnecessary after the forceps has been adjusted and traction has begun.

The construction of this forceps is very simple; there is no complicated mechanism to go wrong. It is a light instrument, not clumsy in appearance, and it combines the outstanding advantages of Sir J. Y. Simpson's original forceps with the added advantages of axis-traction and the minimum amount of compression of the fœtal head. In this forceps, I submit, the advantages of both the old and the new are conserved without detracting from the special features of importance in the construction of *either*. As it stands it is adapted mainly for traction in the cavity and at *the outlet, which practically nowadays* are the only situations where forceps should be used; but, in *addition, it* has potential arrangements for almost perfect high axis-traction by tape attachment should an exceptional case demand it.

The forceps is made by Messrs. Gardner and Son, Edinburgh, who have prepared standardised moulds so as to secure uniformity of the curves and fenestræ.

disappear without the process of dissemination from undiscoverable primary tumours being stopped.

Certain points of interest emerging from the experience of individual centres should be pursued. Sepsis is cited more than once as a strong contra-indication to the use of radium. It is clear that a pyometra may result from its application to an infective cervix if fibrosis and stenosis follow, but even where no damming of discharges is to be feared infected areas appear to be unsuitable for radiotherapy, and this circumstance would seem to call for further study. It is but one of many points which remain unexplained. Our deep ignorance of the rationale of treatment by radium is revealed by the problems set out by the workers at St. Bartholomew's Hospital as still unsolved. Not only is it unsettled whether needles buried in the growth or screened tubes placed on its surface are more efficacious, but it is not even known what is the biological reaction to radiation of the individual cell, or whether the disappearance of the growth depends on the direct action of radium on the individual cell or on its effect on the surrounding structures or body fluids. Considering all these unknown factors, which include even such practical points as to whether a second application is of value or does actual harm, we are tempted to despair of any cal progress until the histological effects of this angerous and powerful weapon are more closely udied. Its haphazard empirical use may benefit dividual sufferers but can lead to no useful general nclusions. It is obvious that insufficient advantage being taken of the facilities for scientific investiga- n afforded by the Medical Research Council. For mple, of a total of 66 cases of sarcoma and lympho- ma treated, only 11 specimens were sent up for ination, though all centres have been repeatedly to supply material from which the results of n treatment might be correlated with the gical features of the tumour. The section on lignant diseases is concerned chiefly with gical conditions and blood diseases. With the former, the conclusion is drawn that completely efficient in creating an artificial e, the usual dose for this purpose being the body of the uterus for 24 hours. This would hardly appear to be substantiated from the London Hospital, where in four lium was employed to produce sterilisa- ote amenorrhœa was not obtained in any ients (who did not, however, become ugh they were treated with 100 mg. wo patients), for 26 hours (one patient), 24 hours with a second application of ours (one patient).

reasonable to expect conformity in and conditions of application at the centres in a therapeutic measure cal stage, but it is difficult to see result from such uncorrelated mbled here. It would seem that an of radium in the future should certain standard techniques, so ined may be to some degree the development of the emana- lies radio-active material in ay provide more uniform ne factor adds an inevitable vidual suffering is being say that the distribution it to the nation, nor need onnexion too closely with on its use in tuberculous ent issue by Dr. PHILIP

## THE SURGERY OF THE SPLEEN.

The spleen is no doubt sometimes useful; it is evidently not necessary; medicine supplies us with illustrations of how it may be harmful. The very lack of comprehensive knowledge of the part which is played by this curious organ in the physiology of the body lends interest to any observations which may be made in human beings who suffer from splenic disease. Very possibly, as has happened in connexion with other bodily structures in the past, the secrets of splenic function will ultimately be deduced by arguing backwards from pathological disturbances. Certain it is that much of the surgery of the spleen has been arrived at quite empirically by clinical observation. The discussion on the surgery of the spleen at the Rome Congress, briefly summarised in another column, brought out very well the position to-day. Operative treatment may be called for when the spleen has been injured, when it has become abnormally loosely connected with its lodgment, when it has been invaded by certain organisms or by the echinococcus, when it is the seat of true tumour formation, and in certain diseases associated with splenic enlargement or changes in the blood. In injuries splenectomy is the procedure of choice, even when the rupture is not large; the organ does not allow of suture in general owing to its friability, and plugging a wound has been frequently followed by secondary hæmorrhage or sepsis. Yet it must be borne in mind that loss of the spleen seems to be a more serious event for the child during its period of growth than for the adult. To combat the ill-effects in children after splenectomy, small transfusions of blood and the administration of splenic or bone-marrow extract have been recommended. When the spleen is abnormally mobile, fixation has brought relief to a number of patients, yet sometimes removal is the better course, and it is a necessary one when torsion of the pedicle has taken place. Abscesses of the spleen are usually best treated by incision and drainage, by the posterior thoracic route when they are at the upper pole, through the abdomen when at the lower one. Only very exceptionally, when the abscess has remained wholly intrasplenic, is removal of the organ the proper procedure.

Most interest, however, circles around the question of splenectomy in those diseases of obscure pathology associated with splenic enlargement and usually with changes in the blood picture. The operation has been tried out sufficiently for us to be able to say definitely that it is absolutely called for in certain of these conditions and absolutely contra-indicated in others, whilst for some its value must remain doubtful until more results are collected. In splenic anæmia, which includes Banti's disease, it is generally accepted that the results are extremely good, particularly before hepatic cirrhosis has come on, but Mayo recommends that the operation should be performed even in the terminal stage as, after it, some patients have got well and lived for years. In hæmolytic jaundice operation is demanded only in the acquired disease and the recovery is usually symptomatically complete and permanent, though the fragility of the red corpuscles may remain. In Gaucher's disease it appears very doubtful whether splenectomy influences very much the course of the malady. In pernicious anæmia the operation has been well spoken of by certain surgeons, and the mortality has been very much reduced by careful selection of the time to intervene and the assistance of blood transfusions. Although transient improvement appears to have followed, it does not seem that the progressive course of the disease has been really affected to an appreciable degree. Splenectomy in purpura hæmorrhagica has produced striking, almost dramatic, results in rapidity of cure and its permanency. The former belief that this depends upon a restoration to normal of the blood platelet count would, however, seem to have been disproved by the experience of Brill and Rosenthal in two cases under their care, for the platelets did not increase in number, yet the patients were cured. Leukæmia has for long been regarded as a disease in which surgery was contra-indicated, but Mayo, in 1924, reported that three patients had lived more than five years and eight for more than three after removal of the spleen; moreover, the danger of the operation has been considerably reduced by previous X ray exposures. Perhaps in the more chronic type of the disease surgery is justifiable and called for.

Many problems connected with the spleen remain unsolved. There is, for all practical purposes, only one surgical procedure possible in the treatment of its diseases—namely, its ablation. The scope of surgery is, therefore, obviously limited. Operative treatment will remain the method of choice in those conditions which arise in the spleen itself, whilst it can be no more than alleviative where the splenic condition is secondary. Only further study in the future will enable us to classify splenic diseases into these two categories correctly.

## HELP IN CHOOSING A CAREER.

Until very recent years, and even yet to a quite large degree, the choice of employment for a child leaving school has been determined by personal liking, parental suggestion, tradition (as typically in the mining and fishing industries), or opportunity. There has been, however, for some time a growing tendency on the part particularly of large industrial firms to make a selection by some method of testing of the most suitable types for their special work, and, on the other hand, on the part of educational and other authorities to discover for what work any particular child is best suited. Vocational selection and vocational guidance thus represent two distinct movements with one end in view. The construction of new intelligence tests, especially those of a non-linguistic type, has greatly contributed to these movements and has at the same time been fostered by them.

The most complete and systematic study of methods applicable to vocational guidance that has so far appeared has just been issued by the Medical Research Council.[1] The work was carried out by the Industrial Fatigue Research Board and the National Institute of Industrial Psychology, and consisted of an intensive study of 100 children (52 boys and 48 girls), who were due to leave school within a year. The main object of the study was to determine the best methods of testing for the purposes of vocational guidance, but in addition, actual advice was given to the parents on the basis of the results obtained, and a further inquiry was made two years later in order to discover the wisdom or otherwise of the advice given. The methods used were therefore largely experimental, and further research may lead to very considerable modifications. That the work was under the general direction of Dr. CYRIL BURT, the psychologist to the London County Council, is a guarantee of its efficiency, and he had four able helpers in Miss FRANCES GAW, who had already standardised a group of performance tests, Miss LETTICE RAMSEY, Miss MAY SMITH, and Miss WINIFRED SPIELMAN, who report individually on their own sections of the work.

---

[1] A Study in Vocational Guidance. H.M. Stationery Office. 1926. 4s.

The schedule of investigation was comprehensive. An inquiry into home conditions, carried out at home, and including family and personal history, and a questionnaire regarding the child's out-of-school behaviour, hobbies, and interests, were the necessary preliminaries. Reference to school medical records was made, but no special medical examination was carried out. This is evidently felt by the director of the research to be a weakness which should be remedied in future investigations. Quite frequently, however, medical contra-indications had to be ignored, and there is certainly some truth in the contention that temporary physical conditions should not be given much weight in the choice of an occupation. The Stanford scale of intelligence tests was employed, supplemented by Miss GAW'S scale of performance tests and Pintner's non-language group test of intelligence. Dr. BURT'S scholastic tests served as a measure of school attainments, and, in addition, certain tests of special practical ability—mechanical, motor, or constructive—were utilised, and some interesting new tests of creative imagination. It was, however, in the estimation of character qualities that the greatest difficulty arose, and some striking comparisons were made in this connexion between the estimates made at one interview by observers to whom the children were strangers, and those made by teachers or others who knew the children well. Emotional qualities were found the easiest to assess by strangers, but with regard to definitely moral qualities, the provisional conclusion is that until more reliable moral tests are available, confidential reports by teachers and parents will have to be accepted.

An inquiry made into the circumstances obtaining after two years in the several occupations yielded interesting results, remarkably satisfactory considering the experimental character of the whole investigation. Of those who obtained work as advised all were satisfied (though not always with the salary), while of those who got work quite dissimilar to that advised, more than half were dissatisfied with the work or its prospects. The conclusion of the director is that the chief weakness of the scheme is imperfect knowledge, not of the children, but of occupations to suit their special aptitudes. The advice, he considers, was not always as good as the results of the tests, because of insufficient "job analysis." The booklet is of great interest, partly as an example of the wider application that is now being made of intelligence tests of different types, and partly from its own intrinsic significance. It is a matter of vast practical importance both to the country and to individuals that each person should find the occupation for which he is best fitted. One may, however, be permitted a doubt whether so comprehensive a scheme of examination is practicable on any large scale. And, although the workers in this investigation have not ignored it, it does seem necessary to insist on the importance of considering a child's own personal desires, where these are strongly marked. These desires do not always coincide with the child's abilities, and it must in some cases be a difficult matter to decide which is to be set aside. Have not the psychologists themselves warned us of the dangers of an uncongenial occupation?

---

**AN HISTORIC ORTHOPÆDIC HOSPITAL.**—The Duke of Devonshire has formally opened Bretby Hall as an orthopædic hospital for Derbyshire. The house, which succeeded that in which the author of the famous "Chesterfield Letters" lived, was built early in the nineteenth century and was ultimately inherited by the late Earl of Carnarvon, whose mother was the only daughter of the sixth Earl of Chesterfield.

# Annotations.

"Ne quid nimis."

## MERCHANT SEAMEN.

THE health of our merchant seamen, or strictly speaking their ill-health, possesses two champions in the persons of Dr. Howard Jones and Fleet Surgeon W. E. Home. Both have drawn attention to the absence of hygienic conditions in the merchant service, to the high mortality—so far as it can be estimated—existing among the men, and to the difficulty of obtaining accurate information as to the exact position. Fleet Surgeon Home has described[1] conditions aboard ship from his own experience, and the picture he has drawn is far from pleasing; yet no effort has been made to contradict it. During the past fortnight he has returned to the charge in our columns in an effort to estimate the serious toll of lives taken annually. The difficulties he has had to face in making his estimates are great; for uncertainty surrounds on the one side the size of the population at risk—i.e., the number of merchant seamen, and on the other the deaths to be ascribed to this population. The Board of Trade issues some information as to deaths among seamen while signed on as crews, but even here the cause of death is often only as correct as a ship's captain can make it. The Board has no information as to deaths among seamen ashore and no longer in active service; that is to say, it has no information as to deaths from those very diseases for which an unhealthy occupation directly prepares the way. The Registrar-General, on the other hand, obtains information as to deaths of seamen ashore, but none as to deaths abroad while on service, and his population at risk is merely that of seamen at home at the moment when the decennial census is taken. It is put forward by Fleet Surgeon Home that between two stools—in this case two Government departments—the case of the merchant seamen is allowed to fall unexplored; the plea seems sound. He asks that the whole matter should be transferred to the Ministry of Health for thorough investigation so that the facts, so far as they can be ascertained, shall be known.

The available evidence displays the merchant service as no health-giving occupation, even after every latitude has been granted for errors in data. But accident risk, with the disappearance of the sailing ship, has greatly diminished, and this is something to the good. Sails, however, made way for the stoke-hole and the lot of the merchant seaman there has been far from enviable. The substitution of oil fuel for coal is now coming to act beneficially, as has been shown by Vigné and Cury.[2] These investigators contrasted the time lost for sickness on Atlantic liners before and after the introduction of oil, and found great advantage on the side of the new fuel. These changes, however, cannot entirely make up for overcrowded and unventilated sleeping bunks, absence of feeding accommodation, and lack of washing facilities. The treatment of the human factor in our merchant service, when its history comes to be written, will rank alongside that meted out to children in our factories a century ago—space for cargoes is still too valuable to sacrifice for human life.

## HOSPITALS AND RECOVERY HOMES.

FOR some years past hospital specialists have been acutely divided as to the effect of recovery homes upon the work and finance of the parent hospitals. On the one side it is argued that these homes decrease waiting-lists, reduce the cost of working, and increase the economic use of the hospital staff and apparatus. That was the line taken by Dr.

---

[1] W. E. Home: Merchant Seamen. John Murray. 1922.

[2] Vigné, O., and Cury, H.: Les Conditions d'hygiène dans les Chaufferies au mazout à bord des navires marchands. Bull. Off. Internat. d'Hyg. Pub., 1925, xvii., 979–89.

F. N. Kay Menzies and Mr. R. H. P. Orde in a paper read at the annual congress of the Hospital Officers' Association last year, which we printed in substantial length at the time (THE LANCET, 1925, i., 1115). Their paper was intended as a refutation of the conclusions of a subcommittee of King Edward's Fund, arrived at, after long and careful inquiry, in 1923. Now Mr. R. H. Maynard, the secretary of that Fund, has addressed a rejoinder to an ordinary meeting of the Association, in which, in arguments based upon the diagrammatic method, he essays to prove that the average cost of treatment in a hospital and in a home of recovery—an intermediate place between the hospital and the convalescent home—is approximately the same. His figures are necessarily complicated and, since it is the sacred duty of any given expert to pick holes in the conclusions of any other expert, we have no doubt that Dr. Menzies and Mr. Orde still have shots in their locker. Meanwhile, it seems probable that, since the circumstances of one hospital differ from those of another, both sides may sometimes be right. In any case, even if recovery homes are, as a fact, in some instances cheaper than hospitals, there is clearly a strong case for their extension. Notwithstanding the high importance of reducing hospital expenditure, finance is perhaps not the best aspect from which to consider the question. The object of hospital treatment is to cure the patient as quickly as may be consonant with thoroughness, and there are obvious, and almost overwhelming, advantages to himself in sending him to the pure air and the reposeful atmosphere of a recovery home as soon as possible. So long as he is in a hospital ward he knows that he is a "case" and his mind is never free from some degree of anxiety and apprehension; once he is in a recovery home he knows that he is getting well. The problem is, therefore, fundamentally psychological and its financial aspect, although full of moment, is of secondary significance. Thus so long as recovery homes do not send up costs they are plainly highly desirable, and the more we have of them the better for the patients. Fine air and quiet rural surroundings are always important elements in convalescence from illness serious enough to have needed hospital, and probably surgical, treatment. Moreover, the hospitals cannot afford to lose sight of the secondary advantage of the quicker emptying of beds.

## A REMARKABLE CASE OF CANCER.

A CASE of cancer of quite exceptional interest is reported by MM. P. Lecène and A. Lacassagne.[1] In February, 1923, a woman had been operated on for advanced cancer of the breast from which a few months after the operation she died with extensive metastases. A fortnight after the operation a student of medicine, aged 21, was told to remove by puncture the fluid which had collected under the scar. In doing so, as the result of a sudden movement on the part of the patient, the syringe broke in the student's hand and the needle which was attached to it was driven deep into the palm of the student's left hand. A small amount of fluid was already in the syringe and some of it was thus injected into the deep tissues of the hand. The student cauterised the wound himself about three-quarters of an hour after the occurrence. During the following two years he noticed nothing. But in February, 1925—that is to say, two years afterwards—he noticed some swelling with diffuse pains. A month later on examination swollen lymph glands could be felt in the left axilla, which were diagnosed as tuberculous in view of the previous history of tuberculous glands in the neck during childhood. The glands were removed for diagnostic purposes. Soon afterwards the swelling in the left hand became more circumscribed and threatened to break through the skin so that an operation became necessary. On microscopic examination it was found that the tissue removed from the hand was a malignant new growth of the nature of a spindle-celled sarcoma and that the lymph glands contained metastatic deposits. A few months later, in September, 1925, four separate nodules appeared in the arm and forearm. They were adherent to the skin. One of these nodules was removed and proved to have the same structure of a spindle-celled sarcoma. The whole arm was then removed by disarticulation at the shoulder-joint, and at the time of publication the patient was quite well.

The paper is accompanied by very clear drawings which show quite clearly that the tumour in the woman has a very different histological structure from that in the man. The former is described as an atypical mammary carcinoma. The several new growths in the man present in all the sites the picture of a typical spindle-celled sarcoma. Pieces of the sarcoma were transplanted into animals of different species (monkey, dog, chicken, mice, rats). The results were all negative. If it is assumed that the neoplasm in the man resulted from the transplantation of living cells, the further assumption becomes necessary that in the course of this transplantation a sarcoma arose from the carcinoma; or, alternatively that, in spite of its histological appearance, the neoplasm in the man was not a sarcoma but an atypical epithelioma, and that the mammary cells had undergone this change as the result of their introduction into a new host. Neither of these two explanations is very convincing. In the many hundreds of animal tumours which have been studied in series of transplantations such changes have never occurred at the first transplantation. The transformation of an epithelioma into a sarcoma has been observed as a very rare occurrence in a few strains of tumours. But even then it was a gradual process, beginning as a mixed tumour in which, on subsequent transplantation, the sarcoma cell, gradually overwhelming by its more rapid proliferation the carcinoma, and not, as in this case, a complete transformation at the first transformation. The third possibility is that we are dealing here not with the reproduction but with the new formation of a tumour. Such an explanation would presuppose some process of microbic infection similar to that postulated by Gye. Whatever the explanation may be the case is of unique interest.

## GUILTY BUT INSANE.

IF the report of Lord Justice Atkin's Committee on Insanity and Crime by no means satisfied the views of the medical profession, it did at least propose one obvious reform of the law—namely, the abolition of the illogical and confusing verdict of "guilty but insane." The Committee's report, upon which we commented when it appeared in 1923, points out unanswerably that the word "guilty" in criminal trials should connote only criminality, the commission of a crime—the very thing which a finding of insanity negatives. Such a finding is a verdict of acquittal, for an accused cannot be "guilty" of a physical act which is not in itself an offence. In the face of the Committee's recommendation it seems hardly credible that the Army and Air Force (Annual) Bill proposes to perpetuate the present illogicality by making it possible for military and Air Force courts martial to give a verdict of "guilty but insane." The official notes on the clauses of the Bill speak airily of bringing military law into line with the Trial of Lunatics Act of 1883. This is as progressive a proposal as if one were to suggest bringing modern ordnance up to the standard of primitive man's bow and arrow.

The story of this legal muddle has been told before, but evidently still requires repetition. The Criminal Lunatics Act of 1800 allowed a jury, when acquitting an accused person after hearing evidence of his insanity, to return a special verdict that he was "insane at the time of the commission of such offence" and that he was being acquitted on account of his insanity; thereupon the accused was kept in custody during His Majesty's pleasure. This worked well enough until, some 80 years later, a madman named Maclean fired a pistol at Queen Victoria. He was found not guilty on the ground of his insanity, and in the heat and sensation of the moment the law was unfortunately altered. Her Majesty, as the recent publication of her correspondence has shown afresh, possessed strong and usually shrewd opinions which she was not afraid to express. Her feelings at her attempted assassination and at the result of Maclean's trial were natural and were doubtless shared by her loyal subjects. How could the man be "not guilty" when she had actually seen him firing the pistol? Accordingly Parliament passed the Trial of Lunatics Act of 1883, which superseded the 1800 enactment and permitted juries to say in such a case "guilty of the act but insane at the time," a finding usually abbreviated into the words "guilty but insane." This is the verdict criticised by Lord Justice Atkin's Committee. The Committee did not press for the immediate repeal of the 1883 provisions, but definitely advised their amendment when opportunity occurred. So far from finding an opportunity for the amendment, the Government now proposes to stereotype the mistake. The Atkin Committee stated the terms of the necessary amendment, and the Army and Air Force (Annual) Bill provides the chance for military law to set an example to civilians.

## ROYAL INSTITUTE OF PUBLIC HEALTH.

THE annual congress of the Royal Institute of Public Health is this year to be held at Bristol over Whitsuntide, under the presidency of the Duke of Bedford. The inaugural meeting will be held in the Great Hall of the University on the afternoon of May 10th and sessions of the sections will continue until May 21st. The week-end will be devoted to excursions in the neighbourhood, and on Sunday the delegates will accompany the Lord Mayor and Corporation of Bristol to the annual "rush" service at St. Mary Redcliffe. The congress will meet in five sections, and a promiscuous number of subjects is to be dealt with. The Section of State Medicine and Municipal Hygiene will hold discussions on Recent Legislation and the Problem of Human Tuberculosis of Bovine Origin (opened by Dr. W. G. Savage), on the Production and Distribution of "Grade A (Tuberculin-tested)" Milk (opened by Lieut.-Colonel C. Maddock, M.D.), and a number of other subjects. For May 21st it has arranged a joint meeting with the Section of Pathology, Bacteriology, and Biochemistry, when a discussion on Cancer will be opened by Dr. J. G. Adami. Other important topics to be dealt with by the Section of Pathology include the Pathology of Epidemic Encephalitis (Dr. J. G. Greenfield and others); Rheumatism (Dr. Carey Coombs), and the Pathology of Tuberculosis (Prof. Lyle Cummins). These subjects will be discussed by many speakers, and, in addition, there will be interesting papers by individual medical men. The Section of Industrial Hygiene is to hear papers on Silicosis by Prof. Edgar Collis, its President, Dr. Norman Tattersall, and Prof. E. H. Kettle. At a joint meeting with the Section of State Medicine Dr. R. A. Lyster will read a paper on Factory Hygiene as Part of Public Health, on which Sir Thomas Oliver and Dr. Arbour Stephens will speak. To this meeting there will also be contributed Studies on the Mechanism of Lead Storage and Excretion, from the Harvard Medical School, by Dr. Joseph Aub and Dr. Donald Hunter. On May 21st the morning session will be devoted to Ventilation of Factories and Vocational Selection. The Section of Naval, Military, Air and Tropical Diseases is to hear a paper by Surg. Captain R. J. Mackeown on the Standard of Public Health of the British Isles as revealed by the Navy Personnel of To-day, with Suggestions for Improvement; and also one on the Incidence and Prevention of Venereal Disease in the Royal Navy. This section naturally covers a large field, as also does that which is devoted to Women and the Public Health, whose chairman is Miss M. F. Townsend. Her presidential address will be devoted to the Care of the Crippled Child and will be followed by papers on the Tuberculous and the Rheumatic Child by Dr. Owen Morris and Dr. A. P. Thomson, and a discussion in which Sir Henry Gauvain and others will take part. At the second session of the section Lady Barrett, M.D., will deal with antenatal organisation, and at the third Dr. Innes Pearce and others will speak on Racial Progress. The final session will be addressed by Miss May Smith and Miss Sheila Barrington on the Psychology of Women Workers, and on the Married Worker by Dr. Christine Murrell. General interest will certainly be felt in the proceedings of the congress, and it is expected that the attendance will be large. A fuller account of the programme and particulars of the facilities offered to members and their friends may be had from the hon. secretaries at 37, Russell-square, London, W.C. 1.

## SMELL.

As Prof. Elliot Smith has often reminded us, primitive land animals lived in a world where perception must have been mostly dominated by the smells of things. In their evolutionary progress vision and hearing became relatively more important. In the higher animals all three are well represented, but in man smell has not made anything like the advance of the other senses, and indeed it seems now to be in much the same place as it was in his remote ancestors. Associated with this primitive condition is the fact that the mind of man has great difficulty in dealing intellectually with the sense of smell and what it perceives. In the *Glasgow Medical Journal* for March, 1926, Dr. J. L. Halliday has an interesting discussion of the position. At present we have not got even a qualitative scale of smells, still less any means for their quantitative measurement. The sense seems to be fatigued extraordinarily quickly, which makes its measurement very difficult by the minimal perceptible dose method which is the only one available. Smells are individual, and no smell seems to have a clear relation to another smell. And while any smell may have the most vivid associations in the mind with other circumstances—evidently the useful state in primitive conditions—the human brain has not yet risen to abstracting smells, so that they can be associated by similarity with one another. There is hence no scale or spectrum of smells, and smells may be said to have no intellectual value. Interest is being taken in various quarters in this sad state of affairs; there is an occasional periodical *Osmics*, and Mr. E. E. Free has an article in the March issue of the *Forum*, and we may look forward with confidence to the time when human ingenuity will denominate smells as it has colours. It is after all not so very long ago that the colour of blood could be described only as being blood-coloured, just as nowadays we can get no further than saying that blood smells like blood. Though, to be sure, people realised that blood is not very dissimilar in colour to some flowers thousands of years before they came to compare the smell of blood to the smell of anything else.

## CONTROL OF URINARY INCONTINENCE BY THE GRACILIS MUSCLE.

EPISPADIAS in the female presents a difficult problem to the surgeon. Dr. Clyde Deming, in the *Journal of the American Medical Association* (March 20th, 1926), has recently described a case in which incontinence was satisfactorily controlled by transplanting the gracilis muscle to form a sphincter. His patient was a woman of 21, whose epispadias had been corrected at the age of 20 with marked improvement of the appearance of the external genitalia, but without change in control. She had a long flaccid urethra without any external sphincter, and only a minute trace of the internal sphincteric fibres. Young's method of operation gave her continence at night, but still she could not hold her water when standing, and a third operation to diminish the calibre of the urethra gave no improvement. At the fourth operation the gracilis was incised between the two areas of nerve-supply and its proximal portion was wrapped round the urethra, sutured back on to itself, and fastened to the under surface of the pubic arch with fine double zero chromic sutures. The wound healed by first intention and the patient could walk about the ward after the third week without any dribbling of urine. The muscle tone was always good and was strengthened by exercises and by electrical treatment. A year later she was able to walk for two hours and to enjoy dancing and social life for the first time. The bladder remained under complete control. The results of other methods of operation, as reviewed by Dr. Deming, have not been very encouraging. He states that among the 30 cases recorded by Novè-Josserand and Gotte only three patients were continent after operation, and there was no appreciable improvement in any of Steiner's series. The region of the perineum provides no muscles with normal sphincter action that can be transplanted into the neck of the bladder, nor are there any straight muscles that can be arranged around the urethra, as the rectus is arranged around a colostomy opening. The pyramidalis, he states, has been used unsuccessfully by Stetinger and Rubsamen, and Rubsamen and Bryosowsky have used the levator ani with some degree of success. One case has been recorded by Novwy of the successful transfer of the adductor and biceps muscles. Perhaps Dr. Deming's procedure will give more satisfactory results. The gracilis seems to be peculiarly suitable for transplanting; its easy accessibility, its double nerve-supply, and the high entrance of the nutrient vessels make the operation an easy one, and it is to be hoped that other surgeons will publish the results of cases treated by this method.

## COLLIP'S PARATHYROID HORMONE.

IN the *Therapeutic Gazette* of March 15th O. H. Petty, W. H. Stoner, and H. W. Schaffer describe clinical application of the recent work of J. B. Collip. It will be remembered that Collip announced some time ago that he had succeeded in preparing an active substance from the parathyroid gland, which on injection caused marked rise in the blood calcium content of normal animals, also administration of this extract was found to cure the tetany of thyro-parathyroidectomised animals. He also noted that by repeated injections it was possible to kill the animals from hypercalcæmia, one of the symptoms being vomiting. In his original publications Collip described very briefly a few clinical tests with his material, but, as he stated, the value of the preparation could not be judged from these. It is very interesting, therefore, to turn to the first published account of a fairly extensive series of cases treated with this preparation. The authors use material made by the Eli Lilly Company. After reviewing the literature very briefly, they proceed to a description of the cases treated, composed mainly of infantile tetany, diabetes, and obesity. They conclude that administration of the hormone is of value in the treatment of infantile tetany, and in some cases of diabetes it is possible to reduce the insulin dosage when the parathyroid hormone is administered. They emphasise the fact that the preparation can never be used without very adequate control by means of frequent blood calcium estimations. As they point out, the estimation requires skill, and they recommend that all workers should employ the same technique since the various methods for the estimation do not yield strictly comparable results. In the same number of the *Therapeutic Gazette* there is an editorial comment on a paper by Lisser and Shepardson which appeared in *Endocrinology*, the authors having treated a case of tetania parathyreopriva with Collip's hormone. The case was a woman of 30 whose thyroid was removed for adenomatous goitre, and unfortunately three parathyroid glands were removed. Shortly after the operation the patient developed typical tetany. The patient was treated by injections of the hormone, and her blood calcium, which previously was low, returned to normal and the objective and subjective symptoms disappeared. They conclude that the material is a true specific.

## POST-VACCINAL NERVOUS DISEASE.

THE international conference on small-pox, arranged by the Health Committee of the League of Nations at The Hague at the turn of the present year, decided to give close attention to the affections of the central nervous system reported in some countries to have followed vaccination. Dr. Levaditi had presented to the Paris Academy of Medicine some months earlier an account by three Dutch observers of 34 cases of post-vaccinal encephalitis (14 of them fatal) which had occurred in Holland over a period of 18 months. The Departmental Committee on Vaccination, appointed by the Ministry of Health, now invites the assistance of all members of the medical profession who are in active practice in this country in the elucidation of this question. The Committee has decided to make a special study during the next 12 months of all cases in which the occurrence of acute disease of the central nervous system (such as meningitis of any kind or origin, encephalitis, polioencephalitis) has been "post-vaccinal"—using this term in the sense that the first symptoms have occurred within four weeks of vaccination. The object of the Committee is to obtain a collection of data sufficient to enable them to ascertain whether there are any features which distinguish cases of acute nervous disease which happen to be "post-vaccinal" (as defined above) from those which are not. The evidence so far available points to certain cases as having been due to encephalitis virus carried by the patient, the effect of vaccination being to activate a virus already present. The request which is therefore made to all practising members of the medical profession is that when called in to any case of disease of the central nervous system with an acute onset they will not fail to inform the Committee as soon as possible of every case in which they have ascertained that vaccination has preceded the onset of the symptoms within a period of four weeks. The intimation should be sent as speedily as possible to the Secretary of the Departmental Committee on Vaccination (Dr. J. R. Hutchinson), Ministry of Health, Whitehall, London, S.W. 1.

## MULE-SPINNERS' DISEASE.[1]

EPITHELIOMA associated with mule-spinning in cotton mills has only been recognised generally within a very recent period, although in THE LANCET of Dec. 2nd, 1911, Mr. John Morley, the demonstrator of anatomy at Manchester, drew attention to the frequency with which a certain class of operatives suffered in this way. The ætiology of the condition was established by the work of Mr. S. R. Wilson, who in the course of an investigation into epithelioma of the scrotum collected a series of 40 cases from the records of the Manchester Royal Infirmary and the Christie Cancer Hospital which had occurred during the ten years previous to the publication of Mr. Morley's notes. The importance of the matter is now widely recognised, and in March of last year Sir William Joynson-Hicks appointed a committee of inquiry, with Sir Gerald Bellhouse as chairman, the other members being Prof. A. H. Gibson, Mr. F. Holroyd, Mr. E. Judson, Sir Thomas Legge, Dr. Archibald Leitch, and Lieut.-Colonel A. B. Smallman, Dr. S. A. Henry acting as secretary. The report of this committee has now been published and a leaflet has been issued from the Home Office simultaneously which sets out the facts for the consideration of all concerned in the cotton industry. The fact that mule-spinners are liable to an affection of the skin which if not properly and promptly treated may become malignant is pointed out, and the need for the serious attention by these operatives to any small warts or ulcers on the skin that may develop in the neighbourhood of the scrotum is insisted upon. Any skin lesion of the part should receive prompt medical attention, since though all warts or ulcers do not necessarily become cancerous the risk is there and should be removed. Frequent washing with soap and water is enjoined in order to keep the scrotal skin healthy.

---

[1] Report of the Departmental Committee appointed to consider Evidence as to the Occurrence of Epitheliomatous Ulceration among Mule-spinners. H.M. Stationery Office. 1s.

A leaflet on the subject of epitheliomatous ulceration in pitch- and tar-workers was issued recently from the Factory Department of the Home Office,[1] which contained substantially the same advice, and as this leaflet was widely circulated among mule-spinners it may be hoped that operatives are aware of the measure of the risks and the methods to avoid them.

THE King has promoted Lord Dawson of Penn, G.C.V.O., K.C.M.G., C.B., to be a Knight Commander of the Order of the Bath, and has appointed Sir Frederick Stanley Hewett, K.C.V.O., a Knight Commander of the Order of the British Empire.

WE are informed by the President of the Surgical Section of the Royal Society of Medicine that when Dr. W. E. Gye reads a paper on May 5th before the Surgical Section on the Origin of Tumours, Mr. J. E. Barnard will give a demonstration on Microscopical Methods.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

Surg.-Capt. R. H. Mornement to the *Vivid* for R.N. Barracks, Devonport.

Surg Lt.-Comdr. W. J. Morris to the *Curlew*.

## ROYAL ARMY MEDICAL CORPS.

Col. R. S. Hannay to be Maj.-Gen., vice Maj.-Gen. H. A. Hinge, who retires on retd. pay.

Lt.-Col. J. W. Langstaff to be Col., vice Col. R. S. Hannay (promoted).

Maj. and Bt. Lt.-Col. T. S Dudding to be Lt.-Col.

### ARMY RESERVE OF OFFICERS.

Lt.-Col. P. H. Collingwood having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

## ROYAL AIR FORCE.

Flying Officer R. L. C. Fisher is promoted to the rank of Flight Lt.

Flight Lt. (Hon. Squadron Leader) E. Brown relinquishes his temporary commission on account of ill-health.

## THE PARKES AND THE ALEXANDER MEMORIAL PRIZES.

The Parkes Prize, open to officers of the Royal Navy, Army, and Indian Army of executive rank on full pay, other than professors and assistant professors at the Royal Naval Medical School and of the Royal Army Medical College, is of the value of 75 guineas in money and a gold medal, and the subject for the next competition will be the Means of Spread and Methods of Control of Bacillary Dysentery. The Alexander Prize, consisting of £50 and a gold medal, is open to executive officers of the Royal Army Medical Corps on full pay, other than professors and assistant professors at the Royal Army Medical College. The subject for the forthcoming competition will be the Various Aspects of Inflammatory Middle-Ear Diseases with Especial Reference to their Relation to Military Service. Essays should be sent to the Hon. Secretary of the Prize Committee for the respective competitions, Royal Army Medical College, Millbank, S.W. 1, on or before Dec. 31st, 1928. Each essay is to have a motto, and be accompanied by a sealed envelope bearing the same motto and containing the name of the competitor.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXX.—THE TREATMENT OF TUBERCULOUS DISEASE OF THE SPINE.

APPROXIMATELY half the cases of tuberculous disease of the spine originate before the age of 5 years, about one-quarter between the ages of 5 and 10, the remainder with decreasing frequency as age advances after the age of 10 years. Spinal caries is, therefore, commonly a disease of childhood, a point of importance in both diagnosis and treatment. The lower dorsal and dorso-lumbar vertebræ are especially commonly attacked. Common predisposing causes are a tuberculous family history, infectious fevers, especially measles, and trauma. There is usually a latent premonitory period characterised by malaise, irritability, easy fatigue, general discomfort with absence of localised pain, cachexia, loss of appetite, and slight pyrexia. Sometimes an abscess forms without pain.

Early signs are the attitude and gait of the patient. Thus when resting the child may lean against some object, occasionally preferring to rest in the ventral position; he may support his hands on his thighs when standing or hold his head if the cervical region is attacked. Squaring of the shoulders, lateral deviation of the head, stiffness in walking or stooping, lordosis, and flexion of the thighs are not uncommon. Muscular spasm and rigidity are usually early marked features, and that before deformity arises. The gait is characteristically guarded, especially in disease in the dorsal region. Pain may be indefinite or absent or referred—e.g., pain at back of head, down arms, intercostal or stomach-ache, or growing pain in legs. It is usually subacute, but at times may be very severe. Occasionally it is starting in character. Pain may usually be elicited by pressure, especially on the transverse processes of the affected vertebræ. Jarring of the head, riding on a rough road, or even walking may cause discomfort or sometimes severe pain. Later angular curvature develops. The first signs may be abscess formation or paraplegia. Early X ray examination should be made in suspected cases. The importance of early recognition—i.e., before deformity arises—and early strict and adequate treatment cannot be too strongly emphasised.

It will be convenient to discuss treatment of tuberculous spinal caries under the headings of General, Local, and Adjuvant. Of these, local measures may be considered as supremely essential, while all are desirable.

### *General Treatment.*

General treatment is concerned with considerations of climate, district, altitude, atmospheric conditions, diet, hygiene, educational and disciplinary measures, all of which deserve attention. Treatment in the country or at the seaside is to be preferred to treatment in towns. A mild but bracing climate is advocated, in a district remote from rivers or swampy grounds, and where the patient may remain out of doors during the greater period of the year. Institutional treatment in a suitable locality is better than treatment at the patient's own home, because constant skilled supervision is more readily obtainable, and also because the patient has the advantage of congenial companionship combined with suitable disciplinary and educational measures. Regular occupation adapted to the needs of a patient condemned to prolonged treatment is of the greatest moral benefit; association with cheerful companions who are themselves progressing towards a cure is encouraging, and helps the patient to realise that prolonged treatment is quite essential, even though he may feel well able to return to a life of normal activity. In this country treatment south of the Thames is preferable to treatment elsewhere, because the climate is milder, outdoor treatment can be more easily obtained, and more sunshine is available. Inland treatment on the chalk downs, at a moderate elevation, is particularly good. Margate and the Isle of Thanet generally have achieved well-deserved popularity because of their bracing character and low rainfall. The southern coast of England is also valuable because of its high sunshine record, but the absence of chalk sub-soil on the coast and greater humidity renders the districts west of Portland less suitable than districts further east. In the winter months treatment in Switzerland at such places as Leysin is popular, the dry, clear air and high sunshine-value having many advocates. Generally it may be said that very young, elderly, or toxæmic patients are best treated inland. In patients responding well, with good physique and good reacting power, marine or mountain treatment accelerates the cure. In the majority of cases combined alternating inland and marine treatment is ideal.

---

[1] THE LANCET, Jan. 30th, 1926, p. 214.

### *Local Treatment.*

Local treatment includes orthopædic measures which aim at the prevention or correction of deformity (as far as is possible in a tuberculous patient), and those surgical manœuvres which complications may necessitate. In acute or progressive caries of the spine three desiderata are called for: (1) dorsal recumbency to ensure rest of the body, (2) immobilisation of the spine, and frequently (3) hyperextension at the site of the disease to prevent the onset of deformity or reduce moderate deformity which may have arisen, and to relieve muscular spasm. Hyperextension is essential in dorsal and lumbar caries if deformity is to be avoided with any certainty. These essentials may be obtained in a variety of ways, of which the one especially favoured by me is the employment of the Berck board and jacket. A Bradford frame is also an admirable apparatus, largely employed in America, and increasingly so in this country. Pugh's frame, which is more elaborate, is very efficient. A plaster bed or a double Thomas splint has numerous advocates, but neither is so readily adaptable to the varying needs of patients, nor can varying hyperextension of the spine be so easily secured with these. In cervical caries the head and neck are usually immobilised by sandbags, but a plaster bed including the head and neck, a high plaster jacket or a box splint for the head with spinal board combined are more efficient. Recumbency with immobilisation should be continued until clinical signs of activity have disappeared and skiagrams indicate recalcification and increased clearness of outline of the affected vertebral bodies. Where paraplegia complicates the condition, head and leg extension is frequently indicated in addition, and often assistance is obtained by the occasional use of counter-irritants, as mustard plasters, at the site of the disease. If within three months the signs of paralysis have not notably abated, some decompression operation, such as aspiration of an abscess through an intervertebral foramen (Calvé's operation), laminectomy or costotransversectomy, should be considered.

Considerable interest has been evoked during recent years by operations devised for the immobilisation of the spinal lesion. Of these, Albee's bone-grafting operation or a modification thereof is most often employed. It is generally agreed that such operations are rarely desirable in children, but may sometimes be usefully employed in adults. Even after these surgical procedures rigorous immobilisation for a prolonged period is essential if satisfactory results are to be obtained.

When dorsal recumbency is no longer indicated, it will be found advantageous to treat the patient in the ventrally recumbent position for increasing periods during the day, fixing his pelvis, placing a wedge-shaped pillow under the thorax, and encouraging voluntary dorsiflexion of the spine. This associated with fresh air and sunlight improves the dorsal musculature, and is of great value in lessening any subsequent tendency to deformity. When ambulatory treatment is commenced an initial period of three months or more fixation in a well-moulded plaster-of-Paris jacket provided with a large ventral window is of value, particularly if many vertebral bodies are affected. Subsequently a removable splint which will counteract the tendency to forward flexion of the spine and afford the spine protection is advocated. Such a splint may be constructed on a cast of the patient's spine, of celluloid or moulded leather, or else a brace, such as Taylor's or a modification thereof, may be employed. Personally I advocate a well-moulded celluloid jacket as most suitable. In cervical or cervico-dorsal caries a jury-mast or occipital and mandibular support may be needed in addition. Poroplastic jackets are hot, clumsy, and not very efficient. In cases of very marked deformity more elaborate measures for reduction of deformity than those described may be indicated.

### *Tuberculous Abscesses.*

A common complication in tuberculous disease of the spine is abscess formation. Such tuberculous abscesses will sometimes absorb or calcify with efficient immobilisation. More frequently they tend to increase in size and should then be aspirated, with due antiseptic precautions, as soon as that is possible. Their spontaneous opening should always be prevented. Neither should they be evacuated by open operation if that can be avoided, as sinus formation and subsequent secondary infection is so frequent a sequela. The common situations for such complicating abscesses are in the iliac fossæ or in the dorsal or lumbar regions. In aspirating a psoas abscess the skin should be pushed inwards with the fingers of the left hand and the abscess grasped between the fingers and the ilium, on the outer side of which the thumb is firmly pressed. The trocar and cannula is then inserted just outside the iliac crest and passed into the abscess. The pus is then withdrawn by means of a special Record syringe. When the abscess has been emptied the aspiration puncture is sealed with gauze and collodion. The operation may have to be frequently repeated, but usually two to four aspirations suffice.

### *Adjuvant Measures.*

Adjuvant measures of treatment include heliotherapy, artificial light treatment, aerotherapy, balneotherapy, vaccine therapy, &c. Of these, heliotherapy and artificial light treatment and aerotherapy have attracted much attention recently, and when judiciously employed are of undoubted help and value. Graduated sun treatment should be utilised whenever possible, assisted by or associated with artificial light when natural sunlight is not procurable. Such treatment accelerates the cure, increases the resistance of the patient to disease, diminishes the tendency to abscess formation, hastens recalcification, and often aids in the healing of sinuses if such exist. Exposure of the nude skin to cold air increases metabolic activity, and the combination of these adjuvant measures, especially when associated with sea-bathing in suitably selected cases, has a notable effect in toning up the patient and assisting in his cure. Vaccines are helpful in the treatment of sinuses recently secondarily infected, but in old chronic sinuses are of little value. Tuberculin has proved disappointing.

## AN ATTEMPT TO PROVIDE A STANDARD DEATH-RATE FOR BRITISH MERCHANT SEAMEN.

BY FLEET SURGEON W. E. HOME.

### PART II.*

IN our endeavour to discover a standard death-rate for British merchant seamen in 1921 we have, so far, no figures from the Registrar-General to help us, but only those of the Board of Trade's Returns, which tell us the deaths that occurred on board and soon after discharge, but do not deal with those that happen later.

In our search we must first (1) follow the Registrar-General's method and get from the Returns for 1920, 1921, and 1922, an average of the deaths that occurred to seamen in their ships. Then (2) we get the number and ages of the seamen from the Board of Trade's Census of Seamen. Next (3) we find the average number of deaths, for the same years, of "All Males (England and Wales)" at their various ages, 15 to 70, rearrange these (4) to suit the grouping of ages in the Census of Seamen, and calculate the death-rates for each group. Then (5) we can find out the deaths to be expected from a population of the same number and with the same age distribution as the seamen, and at the average rates for "All Males, E. and W.," from all causes and from specified diseases and from accidents, when, comparing those due with those that occurred, we shall have some idea whether seamen, in their ships, have a mortality greater or less than the general male population, and in what degree. These are the principles of the tables that follow.

Table I. is extracted from the Returns for 1920–22, the figures being slightly rearranged when necessary. Deaths stated as in part attributable to drink are noted as due to alcohol, and the accidents are distributed into three classes, for which the Returns give facility, according as they result from casualties to ships, accidents on board, or accidents on shore. The total deaths are not so many as in earlier years (1901), injuries are many less, in part because there are so many fewer sailing ships.

Table II. is not printed separately as it is in fact the second column of Table V., showing the age-grouping of the British seamen enumerated (90,025) in the Census; as is remarked in the Return, this was taken in the middle of the coal strike (1921), and the number is less than the year's average; in order that the death-rate may not be stated too high, 100,000 has been taken as the figure representing the average number employed daily throughout 1921, in which year two million fewer tons of British shipping were cleared than in 1920.

Table III. gives the number of "All Males, E. and W.," in five-year periods from 15 to 70, and the three-year average of deaths in each group from certain specified and from all causes, and to the right, for each age-group, the deduced death-rate.

Table IV. shows the figures of Table III. rearranged to correspond with the age-grouping of the Census of Seamen, and the appropriate death-rates for "All Males, E. and W." when so grouped.

Table V. states the age-grouping reported in the Census of Seamen among the 90,025 seamen enumerated, and in the next column the numbers there would be at each age among 100,000; next, under each cause of death there are, to the left the death-rate (All Males, E. and W., from Table IV.) appropriate to each age-group, and to the right the deaths that would have been expected from the group accordingly. These deaths are summed up below, and the totals, being the deaths of each sort expected among 100,000 men, are 100 times the death-rate from each cause, and that death-rate is the standard death-rate we set out to find, being the number of deaths from each cause and from all causes that would be likely to occur among 1000 men of the ages seamen are, had their risk been that of the vast majority of Englishmen, those who live and work in England and Wales and are included in the Registrar-General's great group, "All Males, E. and W.," numbering about 12 million men.

But how many British seamen were there really, and how many were their deaths? The Board of Trade's Census of seamen, taken on June 19th, 1921, gives 90,000; the Board of Trade, in relation to its annual return, estimates them at 173,000; the Seamen's National Insurance Society puts the figure at about 138,000; while the National Sailors' and Firemen's Union thinks the figure should be about midway, more precisely they put it at 117,000; let us take the convenient 120,000 as the average number employed daily in 1921. What, then, about their deaths? They were in all 805 by Table I., and that is 90 per cent. of the average (950), so all the other averaged figures of deaths must be reduced by one-ninth to show deaths in 1921, when there were fewer deaths because fewer men were employed.

We have already seen in Table V. the deaths that would have to be expected among 100,000 seamen—a hundred times their standard death-rate—and these, multiplied by 1·2 (or a fifth added), give the deaths to be expected, at standard rates, among 120,000 seamen, which appear on the next line in the table. On the next line below that are the deaths that actually occurred among 120,000 seamen, distributed among diseases as was usual in the three years 1920, 1921, and 1922. The excess or defect from the expected is set out in the two lines below, whence we learn that employed British seamen in and about 1921, men we always suppose splendidly physically fit, had a death-rate from all causes 12 per cent. higher than "All Males, England and Wales," 10 times higher from enteric fever, 16 times higher from malaria, 180 times higher from small-pox, 50 times higher from alcohol, a dozen times from homicide, nearly double from suicide, and seven or eight times as great from accidents. On the other hand, for pneumonia, and "tubercle, other," their rate is less, five-sevenths, and from tubercle of the lung, only a fifteenth.

The standard death-rate for seamen was 6·485, but the actual death-rate of seamen employed on board ships was 7·20 per 1000, 12 per cent. greater, and, as we have seen, these figures take no account of men dying of disease or accident after discharge from their ships, even if the cause of their death had begun to operate before that discharge. In default of further information, which it is doubtful if any agency other than the Ministry of Health could collect, and that only after some years, the true death-rate of merchant seamen, even in their ships, cannot be exactly stated. In the endeavour to find an approximate figure some arithmetical calculation is necessary. In 1901 the death-rate for British merchant seamen by the Board of Trade's Return was, as we have seen, 13·72—the Registrar-General put it at 21·47. There is in 1921 a great reduction in the Board of Trade's figures, and the death-rate appropriate has become 7·20—a reduction of 48 per cent. The Registrar-General's table for 1921, when it appears, will not show a reduction so great; he deals with older men on whom the improvement in conditions on board ships will produce less effect, and whom the reduction in sailing ships and the accidents therefrom arising do not concern. Therefore his death-rate for seamen will not be so much lowered as will that extracted from the Board of Trade's Returns; let us allow him half of the improvement, from 100 to 76, that will bring down his death-rate for seamen from 21·47 to 16·17. The average then of his and of the Return's death-rates (their populations are sufficiently near) will be 11·68, which, in default of a better, is submitted as the most reasonable approximation to the true death-rate of British merchant seamen, in contrast with

---

* These totals are 100 times the standard death rate for merchant seamen. T = Times.

0·435, their "*expected*" *death-rate, which represents* the much slower rate at which they would have died had they remained at work ashore instead of going to sea. In other words, they appear to die, between 15 and 70, nearly twice as fast (11·68) as their brethren of the same ages (6·43) in the general civil population. The death-rate of the Army in 1921 was 4·82, of the Royal Navy 3·58, and of the Royal Air Force 4·7.

This figure is no doubt in some degree an estimate, but perhaps no merely destructive criticism of details should be put forward, for it is submitted to the profession as not altogether unreasonable. It is submitted also that anyone dissatisfied, and thinking it worth while to say so, should produce a figure of his own and tell us how and why he chose it. That there should be an industry employing annually about 200,000 men under the British flag (say, 140,000 British, 10,000 foreigners, 50,000 lascars), as many men as there are in the British Army, and that the Government Department under which they work cannot give us a death-rate for them, and in years and years has never put out any important information about their health, can hardly be considered a credit to the Department concerned, the Board of Trade. The Board's lightly borne responsibilities in this relation should be taken over (as the Royal Sanitary Institute has asked in each of these two last years, after its congresses held at Liverpool in 1924 and last year at Edinburgh) by the Ministry of Health, when *they would be discharged with satisfaction to the* profession, and with new benefits to the seamen, who deserve them.

# INTERNATIONAL SURGICAL CONGRESS,

## ROME, APRIL 6TH–10TH.

(*FROM OUR OWN CORRESPONDENT.*)

THE seventh Congress of the International Society of Surgery opened at Rome on April 6th under the patronage of H.M. the King of Italy and the presidency of Dr. DAVID GIORDANO (Venice); 306 members attended coming from all parts of the world, and there were 45 British representatives. The proceedings opened with the laying of a wreath on behalf of the Congress on the grave of the Unknown Italian Soldier. Then followed the inaugural meeting in the beautiful salon of the Capitol, presided over by H.E. Signor Benito Mussolini, in the unavoidable absence of the King. The meeting was animated and crowded; addresses were delivered by Signor Mussolini, by the Governor of Rome, Signor Cremonesi, by the President of the International Committee of the Congress, Prof. C. Willems (Liège), by Dr. Giordano, and by the General Secretary, Dr. L. Mayer (Brussels).

Signor MUSSOLINI in his address expressed the welcome of the Italian Government and spoke of the quality of mind and energy of character which must guide the work of the surgeon's hand. He claimed that the art of surgery first rose to the dignity of a science on Italian soil and spoke of the School of Salerno and the four master surgeons who arose from that school—Andrea Vesalio, Wurtzius, Paracelsus, and Ambrois Paré. He referred to his personal experience of the skill of surgeons in the war and said that, while soldiers may rest, there can be no rest from the war upon disease. A final word of cordial greeting concluded an eloquent address. The end of the gathering was marred by the untoward incident which I recorded last week. The excitement in Rome during the rest of the day was intense, and there was a great display of national flags and many processions. The Congress at its *first meeting passed a resolution of great sympathy with Signor* Mussolini.

### *Scientific Sessions.*

The scientific sessions of the Congress were held in the library of the Royal Academy of Medicine at the Policlinico in Via Umberto I. The Policlinico, a well-designed series of pavilions connected by corridors, is the principal hospital of Rome and contains about 1000 beds. The first session was devoted to a discussion on the Treatment of Uterine Cancer in which many speakers took part. Mr. S. Forsdike (London) gave his experience of radium treatment, and the general opinion seemed to be that where radical operation is impossible, radium and deep X ray therapy, both according to modern technique, are of great benefit. At the second session, on the afternoon of April 8th, the subject of discussion was the Treatment of Cerebral Tumours. Opening papers, either read or circulated, emphasised the value of early diagnosis and accurate localisation. Careful primary hæmostasis was insisted on and some speakers condemned "tourniquet" methods. The statistics of Mr. Percy Sargent (London) showed the most favourable operative results in cases of endothelioma; 19 successes in 31 cases of ablation. Dr. de Martel (Paris) referred to the value of ventrilography. Many speakers advocated local anæsthesia. At this session a paper was read by Dr. A. W. Adson (Mayo Clinic) on trigeminal neuralgia. He advocated a straight incision, showed how the motor root could be preserved, and concluded with a cinematograph film showing the sufferings of patients with trigeminal neuralgia. In the general discussion Mr. H. S. Souttar (London) showed an ingenious instrument for opening the skull, the cutting instrument circling round a screw fixed in a trephine hole, and Mr. W. Martin (Cardiff) gave particulars of an intracranial sarcoma apparently cured by radium.

On the morning of April 9th the Congress discussed the Late Results of the Surgical Treatment of Jacksonian Epilepsy. In the opening paper Dr. R. Leriche (Strasbourg) stated his belief that the disease is due to cortical cicatrisation following contusion, and recommended excision of the scar when possible. Otherwise he found radiotherapy and measures to maintain the equilibrium of the cerebro-spinal fluid of benefit. In the discussion which followed Mr. G. Jefferson (Manchester) described his investigation of the after-results in a series of cases of head injury and threw doubt on the traumatic origin of Jacksonian epilepsy.

The subject of the morning session on April 10th was the Surgery of the Spleen. It was opened in very thorough fashion by Prof. K. Henschen (Zurich), who spoke of a large number of conditions in which splenectomy is of value. Dr. E. Beer (New York) gave operative statistics of splenectomy, showing particularly good results in chronic purpura. Prof. A. W. Sheen (Cardiff) spoke of the use of radium emanation, radon, for reducing the size of the spleen before operation. Generally the discussion indicated the increasing range and value of splenectomy. The final session on the same afternoon was on the Treatment of Abscesses of the Liver. Opening papers were read by Prof. L. Dominici (Sassari) and Dr. P. Petridis (Alexandria). The need for accurate diagnosis of the various causes of abscess was emphasised and also the value of emetine in amœbic abscesses.

All the sessions of the Congress were well attended and the difficulty of language was to some extent got over by the frequent use of lantern slides. Operations were watched in the various theatres of the Policlinico and elsewhere on the morning of April 8th. The theatre of Prof. R. Alessandri was crowded to see him do splenectomy, hysterectomy, gastrectomy for ulcer, retro-peritoneal, hydatid, and operation for hydronephrosis. The many who were present had a good view from a high gallery behind a glass screen. Spectators were interested in the use of mercurochrome solution for the skin and in a special gastric clamp. Arrangements and technique in all theatres excited admiration. Other operators were Drs. De Fabi and Margarucci at the Policlinico, Dr. Antonucci at the Ospedale San Giovanni, and Dr. Egidi at the Ospedale di S. Giacomo. At the former hospital avulsion of the phrenic nerve and cervical sympathectomy were performed. Instruments and appliances were exhibited at the Policlinico by Schaerer (Bern), Stille (Switzerland), G. Wolf (Berlin), Rizzol (Bologna), Invernizzi (Rome), and others. Operating tables, Putti's orthopædic table, mechanical bone-cutting instruments, and cystoscopes were features of the exhibition.

### *Social and Business Meetings.*

The social and sight-seeing aspects of the gathering were complete and attractive. A warm welcome and much entertainment was given by the Italian surgeons to their colleagues. On April 9th the Italian surgeons gave a motor trip to Hadrian's Villa, followed by tea and concert at Tivoli. The Congress dinner on the evening of April 10th, to which ladies were invited, was also given by the Italian surgeons and was most successful; speeches were made by delegates from all the countries. The ladies of the Italian surgeons took the visiting ladies for several interesting trips.

At the business meeting on April 9th the Polish invitation to hold the 1929 Congress at Warsaw was cordially accepted. Prof. H. Hartmann (Paris) was appointed president for the 1929 meeting. The question of readmitting German and Austrian surgeons to the Society was brought forward from Japan, and a resolution was passed in a crowded meeting, with six dissentients, which stated that "All the surgeons of the Central Powers who were members of the International Surgical Society before 1920 will be readmitted to the Society, if they accept the statutes of 1920, from the day when their respective countries join the League of Nations." The mention of the statutes. of 1920 is unimportant, merely referring to an alteration in the subscription.

The international, scientific, and national committees were reappointed. The British National Committee is composed of Mr. J. E. H. Roberts (London), Mr. Percy Sargent (London), and Prof. A. H. Burgess (Manchester), Mr. Roberts being the delegate on the International Committee. Dr. Lorthior and Dr. L. Meyer (both of Brussels) were re-elected treasurer and secretary respectively. A ballot was held to decide the subjects for the next congress and the following three were selected, it being within the powers of the Scientific Committee to add others: (1) Causes and mode of production of embolisms; (2) Results of resection of the stomach for gastric and duodenal ulcers; (3) Treatment of Basedow's disease.

The Congress was a great success throughout; the kindness and hospitality of the Italian surgeons and the attractions of Rome were much appreciated. While no outstanding surgical advance was put on record, the scientific discussions showed a high standard of aim and achievement. A final word of admiration should be written of Dr. L. Mayer (Brussels), the Secretary-General, to whose work much of the success of the Congress is due.

## PARIS.

(From our own Correspondent.)

### *Vital Statistics for 1925.*

The French statistical bureau has just issued a provisional report showing for 1925 (as compared with 1924) somewhat fewer marriages, an increase of 17,000 births, more than offset by an increase of 29,000 deaths, and total mortality increasing during the nine last months of the year. Births exceeded deaths by 60,000. The birth-rate remains practically as in 1911–13, and French mortality is higher than that of neighbouring countries.

### *Reorganisation of the Military Medical Service.*

Since the war the French Army Medical Service has confronted growing neglect and lack of enthusiasm, and the personnel is becoming insufficient. Prof. T. Tuffier, who is interesting himself in securing improvement, advocates close coöperation between civilian and military physicians, surgeons, and specialists, and insists that all young men called up for military training should receive some practical instruction in medicine and surgery. His idea is that a medical reserve should be created which can be utilised in case of need. The provision of thorough scientific training in the colonies, better pay, relatively early retirement if desired, proper pensions, and the abolition of undesirable grade distinctions are amongst other things suggested for the encouragement of candidates for the service.

### *Experimental Treatment of Sarcoma with Lead.*

To the *Comptes Rendus de la Société de Biologie* of March 20th N. Waterman contributes from the Laboratoire Anthoni van Leeuwenhoekhuis, Amsterdam, a short study of the effects of treating Rous sarcoma with lead. He used a combination of lead with unsaturated fatty acids. These soaps were only very feebly ionised, and it was difficult to get a stable emulsion. They were well tolerated by fowls on which the experiments were made, but not by rabbits, which succumbed to very small doses. The usual dose for intravenous injection was about 0·05 g. per kg. of body-weight. Chemical analysis of the organs showed a remarkably large deposit of lead in the lungs. These neoplasms, he states, generally cause death from pulmonary metastases, and it was found fowls treated with lead survived some 15–30 days longer than controls, as the metastases developed more slowly. It was noted that the tumours of the animals treated became much less virulent and that their transplantation was rarely possible after treatment. Waterman concludes that slightly ionised lead, in the form of an unsaturated soap, has an unfavourable effect on the sarcoma of Rous.

### *Conditions of Health in French Colonies.*

The League of Nations has recently been studying the subject of tuberculosis in French colonies. In general tuberculosis does not show a tendency to spread in the African colonies, except in towns where the native manner of life has been altered. Alcoholism has diminished the native resistance to the disease. In Madagascar, Tanganyika, and the Sudan tuberculosis spreads more easily among natives living in earthen huts than among those inhabiting well-ventilated dwellings of bamboo and similar material. Tuberculosis in the French colonies is reduced by fresh air, ample light, wide spaces, and physical exercise, as it is elsewhere. The League of Nations has appointed a medical mission for the study of conditions in Senegal, the Sudan, French and Portuguese Guinea, Gold Coast, Ivory Coast, Liberia, and other regions of equatorial Africa, and this mission has just sailed from Antwerp.

### *Foreigners in French Institutions.*

This vexed question continues to clamour for solution. Brandon has presented to the municipal council a plan providing for taxation of foreigners coming from countries not having sanitary conventions with France and for abrogating existing conventions which are unfavourable to France in the present situation. Varenne has pointed out that many of the foreigners are brought in by manufacturers needing workmen and that the manufacturers should share in the financial responsibilities thus created. The Director of Public Assistance has shown that no existing sanitary conventions are satisfactory with respect to the maintenance of foreigners in hospitals, homes, or asylums; these conventions provided only 972 francs for the year 1925, when the expenses incurred for foreigners amounted to 8 million francs. He believes that the best plan would be to prevent anyone with chronic or infectious disease from entering France. Plans for taxation are to be further considered.

### *Medicinal Plant Production.*

A committee, which includes representatives of several Government departments, is studying the question of utilising wild medicinal plants growing in France and promoting their cultivation. It is proposed that premiums shall be provided for yields of good quality, and the plans include effective organisation of small growers.

Dr. M. Tiffeneau, professor of chemistry in the Faculty of Sciences of the University of Paris, has been appointed professor of pharmacology at the Faculté de Médecine. He has been agrégé in pharmacology, and his work is well known, including the synthesis of seneryl and other compounds.

The nineteenth French medical congress will be held at Paris in October, 1927.

A special committee organised by the Ministry of Public Instruction is planning to provide a system of examinations for determining vocational aptitude and capacity in children.

The appearance of a few cases of small-pox in the 15th arrondissement of Paris has caused the posting of warnings and advice to utilise the free vaccination services.

---

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Signed Articles in the Public Press.*

UNTIL recently the appearance in the daily press of articles on medical subjects was quite unusual, but of late years the situation has changed considerably. Editors have become aware that the public, which is accustomed to receive information on every aspect of social and scientific life, may have a legitimate objection to remaining in ignorance of medical matters. The staff of the leading papers therefore includes a medical assistant editor who gives accounts of medical events in a special column at regular intervals, reports on the proceedings of medical societies and congresses, and writes a special article whenever there is an interesting medical event. Apart from this everyday work done by the medical assistant editors, it is customary to ask eminent medical men to write signed articles on vital questions which stand in the forefront of public interest, such as birth control, prophylaxis against venereal diseases, or prohibition. The editors of the leading papers, advised by their assistant editors, take care that only medical men of high professional standing write in their columns, and exclude any who do it for the obvious purpose of advertising. Although, therefore, articles sometimes allude to particular kinds of treatment it has not hitherto been necessary to take any disciplinary action against a medical contributor to a daily paper.

### *Advice to Those About to Marry.*

The importance of a medical examination before marriage has not yet received much recognition in this country. The only measure taken by the Government has been the distribution of a pamphlet in which the advisability of a medical examination is described; this is given to betrothed persons by the registrars before publication of the banns. Recently, however, the Minister of Public Health has issued a circular letter inviting the local authorities to appoint medical men for the examination of candidates for matrimony. The law does not allow any compulsion, and people decide for themselves whether they will undergo medical examination or not. Dr. Hirsch, discussing that question in the Berlin Medical Society recently, said that matrimonial certificates must answer the question whether marriage may be dangerous to the person examined, to the other partner, or to the offspring. The certificate should state whether the proposed marriage is permanently undesirable or whether it should be merely postponed. It must, of course, be left to the discretion of the betrothed whether or not they will follow the advice. Dr. Hirsch discussed the question whether only specially appointed medical officers should be authorised to act as matrimonial advisers, and said that although the average medical man has not at present quite enough knowledge of the very difficult questions which arise, a training in the laws of heredity and in the physiology, pathology, and sociology of marriage would prepare the next medical generation for this work. In Dresden a non-official office was established some time ago by the lecturer of hygiene at the city's technical college for the purpose of advising present and former members of the college; but it had to be placed at the disposal of the general public owing to the demand. The clientèle of the office, indeed, included people of every class. Many of them came because they were aware of the great responsibility they were assuming by marriage; others because their intended wives or husbands had asked them to get a certificate. Men and women came in nearly equal numbers. The Dresden Sick Club has declared its readiness to pay the costs of matrimonial certificates given to its members.

### *German Qualifications in Roumania.*

The Senate of the University of Bucharest has decided that medical students who have studied and qualified in Germany shall undergo an especially severe examination before being allowed to practise in Roumania. It is in explanation of this step that it is made easy in Germany for Roumanian candidates to pass the examination because only very few of them intend to reside in Germany; the universities are said to have no interest in a good training of Roumanians. The association of the German medical faculties has protested against these statements, saying that the German regulations do not allow any difference to be made between foreigners and Germans, and that the individual examiner does not know whether a candidate takes his qualification with a view of residing in Germany or in his own country. The medical faculties are the more astonished by the Bucharest decision, as before the war a large number of Roumanian medical men were trained at German universities without getting into any difficulties with the authorities at home.

### *Cultivation of Spirochæta Pallida.*

Dr. Reiter lately reported to the Micro-Biological Society that he has succeeded in cultivating *Spirochæta pallida* in a fluid nutrient medium composed of rabbit serum and normal saline to which a piece of cerebral substance has been added. From the pure culture obtained he has produced a vaccine which gives a typical reaction on being injected into children suffering from florid syphilis and showing a positive Wassermann test. This reaction is absent, he found, in latent syphilis with a negative Wassermann test. He has tried the vaccine also in patients suffering from general paralysis, especially those who showed no improvement with other treatment, and the result was not only an amelioration of their general state but also the disappearance of the Wassermann reaction.

### *Anniversary of the German Surgical Association.*

The German Surgical Association this year is holding its fiftieth annual meeting; it was founded in 1872, and has met every year since except from 1915 to 1919. At the time of the foundation the number of members was only 130, of whom two are still alive, including Prof. Küster, formerly of Marburg, who attended the recent meeting notwithstanding his advanced age. The present membership is about 2300. To mark the jubilee the meeting was held with great solemnity in the assembly hall of the Langenbeck Virchow House, the common property of the German Surgical Association and the Berlin Medical Society. After a musical introduction by the Berlin Medical Orchestra, the President, Prof. Körte, read an inaugural address comparing the state of surgery at the time of the foundation of the Society with that of present days. Congratulatory addresses were then read by the presidents of the Swiss, Swedish, and Norwegian Surgical Associations, and many congratulatory letters were received from other surgical associations and individuals in every part of the world. The City of Berlin has established an endowment fund for surgical research in honour of the Association. The leading medical papers have issued special numbers, of which that of the *Deutsche Medicinische Wochenschrift* is especially remarkable because it is composed exclusively of contributions by eminent foreign surgeons. The scientific proceedings of the meeting will later be noted.

### *Hispano-American Medical Society.*

A society of the medical men of South America has lately been founded in Berlin under the name of Associacion Ibero-Americana, with the purpose of facilitating the study of medicine in Germany for medical men and students from Spain and South America and of making their stay in Berlin as agreeable as possible. It is remarkable that the diplomatic representatives in Berlin of several of the South American States are medical men. The Minister Plenipotentiary of Columbia was elected honorary president. and the Chargé d'Affaires of Salvador president of the society.

## MEDICINE AND THE LAW.

### *Verdict of Negligence against Doctor for Certifying an Alleged Lunatic.*

The legal arguments in Harnett *v.* Fisher are not available for comment at the moment of writing, but after several days' hearing before Mr. Justice Horridge a decision has been reached upon the facts. It will be recalled that in 1924 Mr. William Harnett recovered the huge sum of £25,000 damages in an action before Mr. Justice Lush against Dr. C. H. Bond, a Lunacy Commissioner, and Dr. G. H. Adam, of West Malling, on the ground of alleged wrongful detention in an asylum for nine years. The House of Lords upset the judgment a year ago. Mr. Harnett has now sued Dr. Henry H. Fisher, of Sittingbourne (who with Dr. Penfold, since deceased, originally certified him on Nov. 10th, 1912, to be a lunatic and a proper person to be taken care of and detained under care and treatment), for negligence in having so certified him. The judge left two questions of fact to the jury: (1) Was Mr. Harnett insane when certified on that date? and (2) Did Dr. Fisher exercise reasonable care in certifying him? The jury has answered both these questions in the negative and has awarded £500 damages. Of the experts called in support of the plaintiff's claim, Dr. Theophilus Hyslop said he did not consider the facts, as set out in Dr. Fisher's certificate, sufficient; he would not himself have given a certificate on those facts. The statements set out were inter alia that Mr. Harnett rambled about religious matters, thought he had a call to rescue persons in Borstal institutions and to draw everybody to Christ, and was deeply absorbed in sexual questions. Dr. Hyslop did not regard these as a safe indication of insanity, nor did he think the certificate as a whole was sufficient ground for detention in an asylum. Dr. Risien Russell gave similar evidence, and expressed the view that Dr. Fisher could not have exercised sufficient care. On the other side, Dr. Fisher was able to call a considerable body of evidence, including the magistrate (Colonel Richard Locke, D.L.), who had signed the reception order and had known Mr. Harnett all his life; Dr. G. H. Adam (defendant in the former proceedings), whose opinion of Mr. Harnett's insanity at the material date was definite; Dr. Ludford Cooper; Dr. E. S. Pasmore, who received the plaintiff into Croydon Mental Hospital in February, 1913; and Dr. J. G. P. Phillips, physician-superintendent of Bethlem Hospital. The judge seems to have expressed an opinion that Mr. Harnett, if he had ever been insane, was now thoroughly recovered. Dr. Fisher, it seems, deliberately avoided exciting Mr. Harnett at the time by cross-examination on the subject of his religious views. There were indications during the recent trial that the learned judge thought the plaintiff should have been made as excited as possible by the certifying doctor in order that there might be no doubt about his condition. The case was, of course, under our law peculiarly a case for the jury, and the jury have given a verdict which, for the present, is final; but, as Mr. Justice Horridge stated in his summing-up, if juries handle this class of case amiss, great difficulty will be found in obtaining doctors to certify patients.

Dr. Fisher stated that the case of Mr. Harnett had not been brought to his mind from the date of the certification in 1912 until some ten years later. The judge agreed that it was a hardship for a doctor to be asked to remember particular cases after so long a lapse of time. The effect of the Statute of Limitations upon the plaintiff's claim is the main legal point upon which judgment has been reserved.

*Dangerous Drugs Act Charges: Sentence of Imprisonment on Doctor Quashed on Appeal.*

Dr. S. G. Connor has successfully appealed against the sentence of six months' imprisonment inflicted upon him at Marlborough-street police-court on four summonses under the Dangerous Drugs Acts and Regulations. The police-court proceedings were mentioned in this column recently, and the sentence of £200 fine and six months in prison (there being three awards of two months' imprisonment to run consecutively) was criticised as unusually severe. On appeal to the London Sessions Dr. Connor, who had pleaded guilty to the summonses in the court below, confined himself to attacking the sentence. It was protested on his behalf that the fines were heavy enough, but that the imprisonment was not a punishment which should be imposed upon a medical man for such an offence. Admittedly the appellant did not keep his books properly, but he had used morphine in a perfectly legitimate manner for the purpose of treating drug addicts, and it was claimed that in several cases he had achieved good results. Sir Robert Wallace, chairman of the appellate tribunal, announced that the bench thought Dr Connor had been guilty of gross carelessness rather than wilful misconduct. The bench quashed the sentence of imprisonment, having regard to the whole case and to the effect of such a sentence upon a medical man.

It has been by no means uncommon for stipendiary magistrates' sentences to be reduced at sessions on appeal. It is unnecessary to discuss whether the stipendiaries have been generally too harsh or the sessions generally too lenient. But if it had been realised as likely that a medical practitioner for a first offence of this kind would receive a heavy fine and a sentence of six months' imprisonment, there would assuredly have been far stronger opposition to the details of the Dangerous Drugs legislation at its introduction.

## EXHIBITION AT THE OPTICAL CONVENTION.

THE exhibition held by the Optical Convention in London last week gave evidence of great advance by British research workers and optical traders during recent years. There has certainly been a sincere attempt by British manufacturers to rival and surpass the work of their competitors on the continent, and, judging by the exhibits at the Convention, the attempt has proved fairly successful, at any rate in so far as the accessories of medicine are concerned. The ophthalmic section shows that practically all the optical instruments likely to be required by general practitioner or specialist can be got from British firms.

The apparatus now available for tests should make it possible to ensure that a lens or lens system fulfils the requirements of the instrument to which it is to be fitted, and should definitely prevent the use of any faulty lens system. In connexion with lens testing the universal lens interferometer exhibited by the National Physical Laboratory and built for them by Messrs. Adam Helger demands special mention. The exhibition of microscopes ranging from a simple folding model by R. and J. Beck, to elaborate microscopes for research and other special purposes, was particularly interesting as a contrast to the collection of microscopes in the historical section. Possibly a great deal still remains to be done, but with the improved methods of illumination now available—a new method of surface illumination, for example, was shown by R. and J. Beck—a steady approach is being made towards the theoretical limits of microscopy.

As a source of illumination for microscopic work the K. B. B. quartz mercury-vapour lamp exhibited by the Thermal Syndicate, Ltd., of Wallsend-on-Tyne, is worth mention. This lamp provides a source of illumination of absolute steadiness and great intensity and it is under complete control. Unlike most mercury lamps, it is not a vacuum lamp, but works under atmospheric pressure, and it requires no mechanical device for starting the arc. It may be operated off a 5 ampere plug in any direct-current house supply, provided that a series resistance is adjusted to suit the voltage. The spectral lines of mercury are well known, and, when fitted with a suitable Wratten light filter, the K. B. B. luminant provides a source of monochromatic illumination specially suitable for microscopic work in the visible, using the green mercury line (λ 5461), or for microphotography using the violet line. As a source of ultraviolet radiations the lamp has much to commend it.

The exhibits of glass manufacture show distinct advance. A recently published catalogue of the oldest established British firm of glass manufacturers describes 112 varieties as against 26 listed in 1914. It is claimed, moreover, that some of these types are far superior to continental glass. The opacity to various radiations is now known with certainty, and some interesting diagrams showing the colours and the intensity transmitted by various glasses were shown. It is now possible to make sure whether a glass is suitable for any given purpose.

Ultra-violet radiations have the property of causing many substances to fluoresce, and this may be used in several ways. One of these was suggested in the section of the exhibition devoted to illusions, when in the course of demonstrations of ultra-violet radiation pictures and diagrams which, when illuminated by daylight, were quite invisible became clearly visible when illuminated by ultra-violet radiations. They may also possibly be useful in analysis, and they are employed in distinguishing genuine precious stones from imitations, and to reveal marks which apparently have been obliterated. The source of artificial light in general use nowadays is the gas-filled incandescent lamp, and this is inconvenient because it alters the more delicate colours of pictures or fabrics. Artificial daylight units go far to get over this objection to electric light Satisfactory illumination is very important, and many things are required of the ideal light Its position, the avoidance of glare, and the intensity of illumination—these are daily problems; and some form of portable photometer, such as the Holophane Lumeter exhibited by Wray, Ltd., of Bromley, Kent, should prove useful to those concerned in the prevention of eye-strain.

Demonstrations of the Fournier d'Albe Optophone by Miss Mary Jameson aroused considerable interest. This instrument is designed to enable a blind person to read an ordinarily printed book. At a demonstration Miss Jameson was able to read part of a newspaper with comparative ease, and she claims to be able to read at a rate of about 60 words per minute.

---

*DONATIONS AND BEQUESTS.*—Mr. William Henry White, Earl's Court-square, S.W., left £1000 each to St. Dunstan's Hostel for the Blind and Dr. Barnardo's Homes.—Salford Royal Hospital has received a donation of £2000 and the Salford District Nurses' Home £100 from the Booth Charities. Other hospitals received £1810.—Mr. Samuel Meggitt Johnson, of Endcliffe-court, Sheffield, besides numerous other bequests, gave £1000 each to the Sheffield Royal Infirmary and the Sheffield Royal Hospital; £250 each to the Jessop Hospital for Women, Sheffield, the Children's Hospital, and the National Children's Orphanage, Sheffield; £200 each to the Totley Orphanage and to the Crookes Orphanage, Sheffield.—Mr. Walter Southwell Jones, Marylebone-road, N.W., left a reversionary bequest of about £25,000 equally between King Edward VII. Hospital, Cardiff, University College Hospital, London, Church Army, the Salvation Army, [illegible] London.

# Correspondence.

"Audi alteram partem."

## WHAT IS ORTHOPÆDIC SURGERY?

*To the Editor of* THE LANCET.

SIR,—Mr. Sampson Handley has chosen (THE LANCET, April 3rd, p. 734) to reopen the vexed question: "What is orthopædic surgery?" using as his text cases shown at the Orthopædic Section of the Royal Society of Medicine. Incidentally the illustrations chosen are singularly inappropriate to Mr. Handley's thesis. The first, Charcot's disease, is commonly treated by the use of some sort of supporting appliance, and the prescription of such an appliance is usually allowed, even by the most pedantic of general surgeons, to be part of the function of an orthopædic specialist. The second, osteomalacia in a child of 16, seems to come within the definition of "deformities arising during the process of growth." The third, secondary ovarian sarcoma of the scapula, was shown by the orthopædic surgeon to Mr. Handley's own hospital; I do not know whether it came from the orthopædic department of that hospital, or if so, by whom it was referred to that department.

But Mr. Handley's real point is something more serious. He would apparently go back to Andry's definition of orthopædics and restrict the orthopædic surgeon to the prevention of deformity in childhood. If he will read Andry's original book "Orthopædia" he will find that in this case the orthopædic surgeon should take over many of the functions of the skin specialist and of the beauty parlour. Present-day orthopædic surgeons cannot allow such a definition to stand; it is time that we stated our position quite definitely and made it clear what we do and what we intend to do.

As an orthopædic surgeon I consider that I am first a fully qualified surgeon in all branches of the subject, but finding that the whole of surgery is too large a subject to be dealt with efficiently by one man, I have given up certain large branches, notably abdominal surgery and surgery of malignant disease (excepting that of the bones), and have agreed to restrict myself to surgery of the bones, joints, muscles, and peripheral nerves, or more generally to surgery of the limbs and spine. This is the "implied bargain" that I made in taking up a specialty, and I think that it is one that is in the public interest. Mr. Handley's "implied bargain" seems to me to be in the interest, not of the public, but of the general surgeon. He would restrict the orthopædic specialty to a field so small that it could not possibly attract men with any ability or ambition. It was such a restriction that brought orthopædic specialists into disrepute 30 years ago when they were expected to confine their work to tenotomies, splinting, and the ordering of an appliance. Mr. Handley says nothing of the other side of the implied bargain. We often see the general surgeon unable to hold his hand when he has the opportunity to carry out such an orthopædic operation as an osteotomy or the correction of a hallux valgus. As a rule the actual operative procedure will then be carried out extremely well, but too often after the osteotomy the correction of the deformity and the fixation of the limb in plaster or in splints, the most important part of the operation, is left to the house surgeon. The hallux valgus is left without after-treatment, because the surgeon does not know that there is any after-treatment.

The real truth is that the general surgeon has almost ceased to exist; the nearest approach to one is to be found in the good provincial surgeon who, working in a smaller community, must be capable of carrying out all sorts of operative procedures with reasonable skill. In London most surgeons are really specialists—i.e., they possess special experience in particular branches of their work. A considerable proportion are specialists in abdominal surgery or in the surgery of malignant disease. It would be better in the interests of the public and of the profession if they would realise this and would acknowledge that there are sections of their work that they can do well and others in which they have little experience. It is not without reason that we hear so much of the work of the unqualified manipulator and bone-setter. Many of the conditions with which they deal are just those in which the orthopædic surgeon (in the present-day sense) is the only member of the profession to gain special experience. But the general surgeon pretends that he knows all about the treatment of a fracture, a sprain, or a muscle injury. Many general surgeons at the present day never handle a fracture themselves, and hardly any gain practical experience in the treatment of minor injuries. There are few orthopædic surgeons who are specialists; they would not for a moment claim that all the surgery of the limbs and spine should pass to them, but they do claim that having given up large (and incidentally remunerative) sections of surgery, they are able to gain a sounder knowledge of the remainder, and that they can thus assist their general surgical colleagues by their experience.

That there are some who think that this is true is, I think, shown by the fact that the Orthopædic Section of the Royal Society of Medicine is very well attended, and that many of those who come regularly are young general surgeons who have no intention of specialising strictly in orthopædic surgery.

I am, Sir, yours faithfully,

Portland-place, W., April 17th, 1926. R. C. ELMSLIE.

## MINERS' NYSTAGMUS: A TENTATIVE THEORY.

*To the Editor of* THE LANCET.

SIR,—In the very complete and interesting article on miners' nystagmus by Mr. G. H. Pooley in your issue of April 10th, and in many previous articles which have appeared in medical literature on this subject, I am not aware that one possible cause of the condition has been given any consideration. I refer to the lowering to great depths at very high speed of those employed in the mining industry.

One statement in Mr. Pooley's article may be utilised to emphasise what I have in mind. He writes (p. 752), ". . . labyrinthine nystagmus, and nystagmus due to cerebellar lesions we know." In diseases of the labyrinth and of the cerebellum in addition to nystagmus we usually, I believe, get vertigo—i.e., sensations of uncontrollable abnormal movements such as of a falling forwards or sideways of the body as a whole. May it not be that the order of things can be reversed and that a sudden prolonged, uncontrolled, abnormal movement of the body as a whole in a rapid vertical descent through space may set up *functional disturbances* of the labyrinth and cerebellum and so produce nystagmus? In one of the local collieries with electrical winding apparatus the depth of 880 yards is reached in 60 seconds, or a virtual fall of the human body through space at the *middle* of the descent at the rate of about 35 miles per hour. Only in the mining industries does this abnormal vertical movement of the body occur and at such a rate.

Nature, I feel sure, in the genus homo, never provided for such an upset of the body equilibrium, and therefore I suggest that the cerebellum, the labyrinth, and the closely related eye muscles are seriously upset, that the effect of this is nystagmus, and that it does not wear off daily for many hours after reaching the pit bottom. Is it surprising then that Mr. Pooley states (p. 752): "Roughly, 50 per cent. of all actual coal-getters had gross oscillation of the eyes. . . . coal-getters had traces . . ."? How many more would have had traces . . . ."? Note the "How many more." Further, be it noted that Dransart's tests for the degree of nystagmus are made in the vertical plane of eye movements corresponding to a vertical fall through space. Again I am informed that the velocity at which the men are lowered is much higher nowadays than in the 'seventies and to much greater depths. Might not this be the cause of the greater incidence in present times? If the rate at which the men are lowered is the cause of the disease, then the remedy is obvious.

There is such a pother as to whether deficient illumination or some toxic gas is the actual cause of miners' nystagmus that I humbly venture the above tentative theory, at least as a potent factor.

I am, Sir, yours faithfully,
J. PROSSER DAVIES, M.B., B.S. Lond.
Cardiff, April 16th, 1926.

## THE NEW HEALTH SOCIETY.

*To the Editor of* THE LANCET.

SIR,—We are very grateful to you for your appreciative article and kindly criticisms of the activities of the New Health Society. I am sure you will realise the aim of this Society is to reach the mass of the public who are sadly lacking in the knowledge of the *rudimentary laws of health.* The motto of the members of our Council is simplicity. We do not consider that controversial or medical questions should occupy a very prominent portion in the pages of our *Bulletin*, believing the proper place for such matters to be the pages of THE LANCET.

In the early days of health propaganda, the necessary reiteration of the four primary laws of health of the body, as so simply and lucidly put by one of our Council, as fresh air, fresh water, fresh food, and a good drainage system, must have appeared monotonous to the instructed.

We are always pleased to receive kindly criticism from a journal so justly popular, not only with the medical profession, but also with the lay public.

I am, Sir, yours faithfully,
W. ARBUTHNOT LANE,
Sentinel House, Southampton row, W.C., President.
April 16th, 1926

## DIABETES, A RECOVERABLE DISEASE.

*To the Editor of* THE LANCET.

SIR,—I should like to congratulate Dr. Chapman and Dr. Percival upon the success they have had with patients who were treated upon the lines I advocated even before insulin was available in this country. In February, 1923,[1] I expressed the view that it was not hypoglycæmia that would prove the greatest danger when insulin could be given by all who practised medicine. The real danger would be the administration of too little insulin *for the diet* prescribed; this would lead to the sugar in the blood being kept at too high a level, and the pancreas would degenerate completely.

This prophecy has proved correct and has been the experience of those who have either adopted the view expressed by Prof. H. MacLean in May, 1923,[2] that diabetes mellitus is essentially a *progressive* disease, and therefore not attempted to keep the blood of their patients below some arbitrary percentage, or who have not had the facilities to do this. In February, 1925,[3] I published curves of the rise in the sugar in the blood after intravenous injections of sugar before and after courses of insulin which had rendered the patients *hypoglycæmic* for several weeks. These demonstrated an improvement in the sugar-burning and/or storing mechanism.

Although more than 450 cases of diabetes mellitus have been treated with insulin under my supervision, I should hesitate to express definitely the view that the disease is recoverable or that it is essentially progressive. The term diabetes mellitus *is applied* to several different conditions. The proof of this lies in the fact that some patients suffering from hyperglycæmia without any ascertainable infection do not react to insulin even when it is injected in enormous doses. Again occasionally, it is true rarely, a patient who has reacted to insulin loses the power of doing so; this loss may be sudden and not due to any infection that can be recognised at an autopsy.

One should be extremely careful not to confuse the issue by *including in evidence in favour of recovery* from diabetes mellitus any case in which there has been recovery from an infection. Cases of mild hypoglycopyresis appear to be suffering from true diabetes mellitus when absorbing toxins.

I am, Sir, yours faithfully,
Portland place, W., April 14th, 1926. O. LEYTON.

## BLOOD-SUGAR IN ENCEPHALITIS.

*To the Editor of* THE LANCET.

SIR,—We have read with interest the article of Dr. McCowan and others (THE LANCET, April 17th, p. 802) on blood-sugar in encephalitis lethargica; the more so, as we have recently made similar investigations with entirely different results. *Of the five cases in which,* amongst other things, we studied the glucose tolerance, basal metabolism, and nitrogen balance, the first was of a boy recovered from the acute stage of the illness and without Parkinsonism and the other four were *Parkinsonian* in type; of these four, one showed pronounced stupor, two were typical examples of bradykinesia, and one was myoclonic. In all five the glucose tolerance, as shown by serial estimations of blood-sugar by the method of Folin and Wu, was definitely normal in type, without hyperglycæmia, and in one case (the stuporose) slightly suggestive of increased tolerance In this last case, which appears to be similar to Dr. McCowan's case whose glucose tolerance is illustrated by his Fig. 4, the flatness of our curve is in marked *contrast* to his parabola. As determination of nitrogen and basal metabolism in these cases also gave normal results, the total N output being always less than intake and the basal metabolic rate showing very little variation from normal, we feel that our findings in the matter of glucose tolerance are, in some degree, confirmed.

We are, Sir, yours faithfully,
H. S. PEMBERTON.
Liverpool, April 19th, 1926. W. D. JEANS.

## IONIC MEDICATION.

*To the Editor of* THE LANCET.

SIR,—In your annotation on Mr. Morphy's valuable paper on Ionic Medication in Dentistry, as well as in his paper, there is a point which I think should be *corrected* The term "*nascent*" should be limited to the property shown by ions as they become atoms—that is, when they are about to give up an excess charge of electrons or are about to take up *electrons to make up* a deficiency. This occurs, as the primary or secondary effect of an electric current, at the contact of ions with metal or carbon electrodes with which they are not *entering into chemical* combination. There is no evidence to show that when ions form fresh compounds in the tissues there is any action due to a "nascent" condition. I believe Mr. Morphy adopted this suggestion from the paper by Dr. David Campbell, to which he refers. Dr. Campbell in that paper used the term "nascent" for conditions to which, in my *opinion, it is not* applicable.

I am, Sir, yours faithfully,
Devonshire-place, W., April 19th, 1926. A. R. FRIEL.

## NEURITIS AND NEURALGIA.

*To the Editor of* THE LANCET.

SIR,—Your reviewer in last week's issue is "surprised to find no apparent description of, or reference to, metatarsalgia . . ." which he very kindly goes on *to say appears* to be the only neuralgic condition not described in my book. If he will turn to the last chapter on Neuro-Fibrositis, page 400, line 6, he will find the reference to *metatarsalgia which he has* overlooked.—I am, Sir, yours faithfully,

WILFRED HARRIS.
Wimpole-street, W., April 20th, 1926

# Obituary.

## JOHN WILLIAM SMITH, M.B. Edin., F.R.C.S. Eng., D.L.

Mr. J. W. Smith, who died at Ingleton on April 13th at the age of 61, was once a familiar figure in Manchester medical circles. He was the eldest son of Mr. Thomas Davidson Smith and was educated at the Friends' School, Lancaster, and at Lancaster Grammar School. Proceeding to the University of Edinburgh he graduated in medicine with first-class honours in 1886 and in the same year qualified as M.R.C.S. After a few months' study at Vienna he returned to England and went to Manchester in 1889 as junior demonstrator in anatomy under the late Prof. A. H. Young. His bent, however, was towards surgery, and having become F.R.C.S. in 1890 he was elected resident surgical officer at the Manchester Royal Infirmary, a post which he held for three years.

During the South African war he served for six months as honorary lieutenant in the R.A.M.C., and on his return in 1901 was elected assistant surgeon to the Manchester Royal Infirmary, becoming surgeon in 1910. Mr. Smith was also assistant surgeon at the Christie Cancer Hospital and visiting surgeon to the Charlton Union Infirmary. At the University of Manchester he became lecturer on operative surgery in 1904, and on the retirement of Prof. G. A. Wright in 1911 was appointed professor of systematic surgery. In this appointment he continued till 1922, when gradually failing health enforced his retirement. From his Edinburgh days he took a keen interest in the work of medical societies; in the year of his graduation he was president of the Royal Medical Society of Edinburgh, and at Manchester he was president of the Medical Society in 1919. For several years he acted as medical referee under the Workmen's Compensation Act, and his wide surgical experience and knowledge of compensation claims brought him the appointment of consulting surgeon to the Corporation Tramways Committee. Following his experiences in South Africa he directed his attention to military affairs at home, and for many years before the war was a lieutenant-colonel in the R.A.M.C. (T.F.), commanding the East Lancashire Field Ambulance. At the outbreak of war he was appointed commanding officer of the Second Western General Military Hospital, and as the number of institutions and beds increased it became his duty to oversee the administration of more than 160 hospitals with a total accommodation for some 16,000 patients. His services during the war were recognised by his appointment as deputy-lieutenant of the County of Lancaster. Mr. Smith's excellent training in anatomy was of the greatest use to him in his career. He devoted much attention to intestinal surgery, and especially to rectal carcinoma, which he treated with remarkable success. He was a careful and competent surgeon and his reputation in and around Manchester stood high.

In 1910 Mr. Smith married the daughter of Mr. Henry James Mason, of Holland Park, London, who survives him with one son and one daughter.

## JOHN EDGAR PERCIVAL SHERA, M.D. Brux.

Dr. J. E. P. Shera, who died at Wells on March 24th after a long illness at the age of 52, was educated at Dublin, took the Irish triple qualification in 1895, and graduated as M.D. at the University of Brussels in 1903. He held a number of asylum appointments, including that of senior medical officer to the Somerset and Bath Mental Hospital at Taunton, and was justices' visitor for Somerset under the Lunacy and Mental Deficiency Acts. After service with the R.A.M.C. at Salonica and in Russia he returned to England, and six years ago succeeded Dr. Pope as medical superintendent of the mental hospital at Wells.

---

# Medical News.

Royal College of Surgeons of England.—At a quarterly meeting of the Council of the College held on April 15th, Sir John Bland-Sutton, the President, in the chair, the Walker Prize of £100 was awarded to Dr. William Ewart Gye in recognition of his work in advancing the knowledge of the pathology and therapeutics of cancer during the past five years. The award was made in pursuance of the following report from the committee appointed to advise the Council in the matter:—

"The work of Dr. Gye, which has been very materially assisted by the optical researches of Mr. J. E. Barnard, F.R.S., promises to throw light upon the hitherto unsolved problem of the causation of malignant disease. Taking as his starting-point the pioneer work of Peyton Rous upon fowl sarcoma, Dr. Gye produced from this tumour, by different methods, two fluids. Neither of these fluids when inoculated alone produced a tumour, but an inoculation of the mixed fluids in a healthy fowl was followed by the appearance of a sarcoma. The experimenter inferred in his further work that to produce a malignant growth two factors are necessary, first a living virus which appears to be of extreme minuteness, and secondly a chemical factor peculiar to each species of animal and effective only in that species. Dr. Gye has succeeded in cultivating this virus in vitro. Further, by a series of substitution experiments, he has shown that there can be obtained from human carcinoma and from malignant tumours of the rat and mouse a virus capable of acting with the 'specific factor' of the fowl to cause fowl sarcoma.

"These experiments, pursued with great patience and acumen over a long period and still in progress, suggest new and hopeful lines of attack upon the problem of the cause of malignant disease. Though it cannot yet be said that they have found practical application, they have already given to cancer research such a great stimulus, and such a new direction, as to justify the committee in recommending Dr. Gye for the Walker Prize."

The Cartwright Medal with an honorarium of £85 was awarded to Dr. James Sim Wallace, L.D.S., for his essay on Variations in the Form of the Jaws with Special Reference to their Ætiology and their Relation to the Occlusion of the Dental Arches. The subject for essays for this prize for 1926–30 will be the Ætiology, Pathology, and Treatment of Periodontitis (Pyorrhœa Alveolaris).—The subject for essays for the Jacksonian Prize for the year 1927 will be the Pathology, Diagnosis, and Treatment of Bronchiectasis and Abscess of the Lung.—Prof. Ernest W. Hey Groves, of the University of Bristol and the General Hospital, was appointed Bradshaw lecturer for the ensuing year.—Mr. George Buckston Browne, of London, and Mr. Thomas Herbert Bickerton, consulting ophthalmic surgeon to the Liverpool Royal Infirmary, were elected Fellows of the College.—Diplomas of member were conferred upon the following candidates who have passed the requisite examinations and complied with the by-laws:—

Eric L. Fothergill, Oxford and St. Thomas's; John Gray, Cambridge and Guy's; Alfred Hobson, M.B., Ch.B. Birm., Birmingham; Mustafa M. Raouf, Cairo and St. Thomas's; Sidney T. Seccombe, St. Thomas's; Charles C. Ungley, Durham.

Licences in dental surgery were also conferred upon the following:—

Cecil Fine, Cape and London; H. Schluchmann-Janssen, Cape and Royal Dental.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.—The following candidates have passed the Triple Qualification Examination:—

Final Examination.

Francis D. R. Wylie, Harry Ellison, Basil J. Hallion, David J. Allan, John L. Clark, Robert W. Schuch, John L. I. D'Silveira, Walter C. Heslop, Thomas D. Gould, Richard A. B. Leakey, Wellwattage *Liveris Perera* Dassanayake, Minnie F. Varley, Catherine Millar, Robert J. Snodgrass, Frank G. Sinclair, John Daly, Herbert C. V. de Silva, Edwin H. Eastcott, Nawalage John A. Cooray, John P. T. Mills, Max Camrass, George M. Johnson, Joseph Walker, Ellis Stungo, Charles L. E. P. Samarasekara, Charles E. Millen, and David Isaacs.

*Medicine.*—Ching Eng Toh, William Robinson, Graeme M. Macintyre, Peter D. Samarasinghe, Hewadewage Julius Fernando, Arthur G. Farquharson, John A. Mains, Arthur H. Edgar, Owain ap Vychan Jones, John B. Hutchison, and Emile Fischbacher.

*Surgery.*—Wilfred L. G. Jewitt, Arleigh W. Scott, Eric A. Y. MacKeown, Charles H. A. S. B. Panlickpulle, Hewadewage Julius Fernando, Ann J. Brown, Thomas M. Ormiston, Leo Checchi, James G. Currie, William Jackson, Archer W. Dunn, and Kanailal Palit.

*Midwifery.*—Carapiet Aviet Basil, Samuel A. B. Hosang, Ernest P. Tulloh, Thomas A. P. Wynter, Wilfred L. G. Jewitt, Peter D. Samarasinghe, Oswald D. Beetham, Charles H. A. S. B. Panlickpulle, David R. Wark, Ann J. Brown, Thomas M. Ormiston, Emma C. M. Muschamp, Leo Checchi, James G. Currie, Archer W. Dunn, Charles V. Harrison, Joseph R. R. Nicholas, Frederick T. Shadforth, Kudyar Marimuthu Rama Swami, George V. Boyle, John B. Hutchison, Edward C. Davies, and James T. M. Symington.

*Medical Jurisprudence.*—Robert J. Ormsby, Hugh N. Maclachlan, Duncan Gould, Robert G. Paul, George M. Johnson, George R. Gardner, Gerald M. Fox, Stephen E. W. Boland, William Robinson, Mohamad Mahmoud Farghaly, and John E. Mulholland.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At recent dental examinations, out of 20 candidates entered, the following 12 passed the Final Professional Examination and were granted the diploma L.D.S. R.C.S. Edin.:—

John H. E. Sanderson, Daniel A. Pauw, William P. Baxendine, Charles F. G. Reid, George F. Downey, Jacob S. Taback, Herbert F. Simpson, David S. Johnston, William Dyce, Ian G. Sutherland, Hector Archibald, and Isaac Stein.

The following candidates passed in the subjects of:—

*Pathology.*—David Dunnet, Edward L. Calder, and Richard V. P. Campbell.
*Medicine.*—Edward L. Calder, Margaret Leslie, Richard V. P. Campbell, and Hugh Linn.
*Surgery.*—Margaret Leslie, Richard V. P. Campbell, Thomas T. Jamieson, and Hugh Linn.
*Dental Subjects.*—John McAra.

THE Chesterfield Medal at St. John's Hospital for Diseases of the Skin and the London School of Dermatology has been awarded to W. Upton, M.B., Ch.M. Sydney.

INDIAN MEDICAL SERVICE DINNER FUND.—The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 16th. Major-General Sir R. C. MacWatt has been invited to take the chair. Tickets and all particulars may be obtained from the joint hon. secretary, Colonel J. J. Pratt, 18, Nevern Mansions, Warwick-road, London, S.W. 5.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual provincial meeting of the Fever Hospital Medical Service Group will be held at the Medical Institute, Great Charles-street, Birmingham, on Friday, April 30th, at 2.15 P.M., when Mr. F. Brayshaw Gilhespy will read a paper on Some Aspects of Ear and Throat Work in the Acute Infections.

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES.—Prof. Leonard J. Russell will give a course of nine lectures on Science and Philosophy on Tuesdays at 5.30 P.M. at Bedford College for Women, Regent's Park, beginning April 27th. Particulars of the course can be obtained from the director of the Institute, 88, Kingsway, London, W.C. 2.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Mr. Neville Chamberlain, Minister of Health, will open the Society's pharmacological laboratories on Wednesday, May 5th, at 3 P.M. These laboratories have been established for the testing of the substances to be scheduled under the Therapeutic Substances Act, 1925. These include digitalis, strophanthus, ergot, pituitary extracts, and other drugs whose purity and potency cannot be determined by chemical means. The work will be carried on by the Society with the assistance of an advisory committee including Sir Humphry Rolleston, Sir Nestor Tirard, Dr. H. H. Dale, and Prof. W. E. Dixon. The director of the laboratories is Dr. J. H. Burn.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Tuesday, April 27th, at 2 P.M., Mr. Gwynne Williams will give a special afternoon demonstration in clinical surgery at the Royal Northern Hospital, to which all members of the Fellowship and General Course ticket-holders are invited. The last week of the course in urology at St. Peter's Hospital begins on April 26th; clinical work in the hospital will be available every afternoon, and a special lecture. The Royal Waterloo Hospital will hold a three weeks' course in medicine, surgery, and gynæcology, beginning on May 3rd, which will include lecture-demonstrations. On the same date a special course will start at the Central London Throat, Nose and Ear Hospital. This will be divided into two parts, clinical and operative, the latter occupying an hour and a half each morning. The two parts may be taken together or separately. On May 9th the Infants Hospital will begin a two weeks' course in diseases of infants, the first item being a morning visit on Sunday to the V.D. Centre, Thavies Inn, Holborn. On week-days the sessions will begin at 2 P.M. at the hospital. The Royal Westminster Ophthalmic Hospital is holding a course for the first three weeks of May, which will include clinical instruction daily at 2 P.M., and a special demonstration three times a week. Also from May 3rd to 28th there will be a course in psychological medicine at the Maudsley Hospital. Various forms of clinical instruction are open and special lectures will be given each afternoon. Between the same dates the London Lock Hospital will hold a course in venereal disease, with clinical work daily, and special lectures. Copies of all syllabuses, of the General Course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

ILLUMINATING ENGINEERING SOCIETY.—A meeting will be held at the house of the Royal Society of Arts, John-street, Adelphi, on Thursday, April 29th, at 7 P.M., when Dr. James Kerr will open a discussion on School Lighting: Modern Requirements and Recent Progress.

NATIONAL MILK CONFERENCE.—Under the presidency of the Minister of Health a conference on Milk in Relation to Public Health will be held in London on Tuesday, June 8th. It is convened by the National Clean Milk Society, and particulars of membership may be had from Miss J. E. Holland, 3, Bedford-square, London, W.C. 1.

TRINITY COLLEGE, DUBLIN: MONTGOMERY LECTURES.—Dr. T. Harrison Butler, of Birmingham, delivered two Montgomery lectures in Trinity College last week, his subject being the Clinical Use of the Slit Lamp. He had a large audience for both lectures, including many outside the ranks of ophthalmic specialists. He demonstrated the use of the lamp in clinical work at the Royal Victoria Eye and Ear Hospital during his visit.

SEAMEN'S HOSPITAL SOCIETY.—In a brief note which appeared in our last issue on the work of this society, the accidental omission of a line made it appear that the statement, "There are now two resident medical officers, the nursing staff has been enlarged, and the hospital has been recognised as a nurses' training school," applied to the parent hospital at Greenwich and not, as it should have done, to the Tilbury Hospital, which is a new branch of the society's work. At the Dreadnought Hospital itself there are five resident medical officers and, of course, a well-established training school for nurses.

THE LATE SIR SYDNEY RUSSELL-WELLS.—The presentation portrait of the late Sir Sydney Russell-Wells, painted by his nephew, Mr. John Wells, R.I., will be unveiled by Sir Humphry Rolleston in the staff room of the Dreadnought Hospital, Greenwich, at 3 o'clock on Tuesday, May 4th. The portrait, which has been subscribed for by friends and colleagues of Sir Sydney Russell-Wells, was on view at the Alpine Gallery in March. It represents him in his robes as Vice-Chancellor of the University of London. Any friends of the late Sir Sydney Russell-Wells who desire to be present at the ceremony may obtain cards of invitation on application to Prof. R. Tanner Hewlett, at the Seamen's Hospital, Greenwich.

UNIVERSITY OF LONDON.—Among the recently appointed teachers of the University are Dr. Leonard Hill, Captain S. R. Douglas, and Dr. H. H. Dale, who will be teachers respectively of Physiology, Experimental Pathology and Physiology, Pharmacology and Bio-chemistry at the National Institute for Medical Research.

*Institution of University Chairs.*—It has been resolved to institute, in accordance with the Regulations on University Titles, a Chair of Bacteriology and Immunology tenable at the London School of Hygiene and Tropical Medicine, and a Chair of Epidemiology and Vital Statistics tenable at the same school.

The *D.Sc. Degree in Statistics* has been conferred on Egon Sharpe Pearson (University College) for a thesis entitled Bayes' Theorem examined in the Light of Experimental Sampling (*Biometrika*, Vol. XVII., Parts 3 and 4, December, 1925).

It has been resolved to institute an *Academic Diploma in Anthropology*, and regulations therefor will be issued in due course.

Sir Holburt Waring has been appointed to represent the University at a meeting to be held this month, to consider the steps which should be taken to organise an appropriate celebration of the centenary of the birth of Lord Lister in April, 1927.

A course of three lectures on Fitness for Work will be given by Mr. T. H. Pear, professor of psychology in the University of Manchester, at the London School of Economics on May 31st, June 1st and 2nd, at 5 P.M.

*Thomas Smythe Hughes Medical Research Fund.*—The Senate will proceed shortly to consider applications for grants from this fund, which are allocated annually for the purpose of assisting original medical research. Applications must be received not earlier than May 1st and not later than June 15th next, and must be accompanied by the names and addresses of not more than two persons to whom reference may be made. Further particulars may be obtained from the Academic Registrar.

The *Rogers Prize* of the value of £100, open to all persons whose names appear on the Medical Register of the United Kingdom, will be awarded for an essay or dissertation on the Value of the Various Methods of Investigating Diseases of the Pancreas. Essays or dissertations, addressed to the Vice-Chancellor, must reach the University on or before April 30th. Further information may be obtained on application to the Academic Registrar.

**MEDICAL GOLFING SOCIETY.**—The final of the knock-out tournament will be played between Mr. Joseph Cunning, who defeated Squadron Leader A. J. Brown, and Dr. E. Ravensworth Hart, who defeated Dr. D. S. Gordon.

**MAUDSLEY HOSPITAL, DENMARK HILL.**—A series of six clinical demonstrations of Types of Mental Disease will be given at the hospital by Dr. Edward Mapother on Wednesdays, commencing May 5th, at 2.30 P.M. The syllabus will be found in our advertisement columns (p. 44).

Major-Gen. Sir Richard Luce, F.R.C.S., will preside at the annual meeting of the Medical Mission Auxiliary to the Church Missionary Society to be held at the Central Hall, Westminster, on Wednesday, May 5th. Tickets for admission may be had from the Loan Department, C.M.S., Salisbury-square, London, E.C. 4.

**BRITISH SCIENCE GUILD.**—The annual meeting of this Guild will be held at the Mansion House on Thursday, April 29th, at 4.30 P.M., when the speakers will be Lord Askwith, Dr. E. F. Armstrong, F.R.S., Captain P. P. Eckersley, M.I.E.E., and Sir Richard Redmayne. The programme includes addresses upon the coal-mining industry, dyestuffs, and broadcasting.

**CONFERENCE ON MENTAL WELFARE.**—A conference, arranged by the Central Association for Mental Welfare, will be held on Thursday and Friday, May 20th and 21st, at the Central Hall, Westminster. The subjects of discussion will be the Proper Care of Defectives Outside Institutions; Borderland Cases; The Training of Teachers for Special Schools; and Encephalitis Lethargica. Details may be obtained from Miss Evelyn Fox, 24, Buckingham Palace-road, London, S.W. 1.

**UNIVERSITY OF LEEDS.**—New premises have long been needed for the thriving school of dentistry which is a department of the University, the hospital work now being done at the General Infirmary. A site valued at £8000 has been provided by the authorities of the General Infirmary, and the Dental Board have promised a grant of £5000 if the balance of the cost of building is obtained from other sources. The sum of £2000 has already been received from the honorary staff of the dental school, and other subscriptions are invited to ensure early completion of the two-storey building, the designs for which have already been accepted.

**VOYAGES D'ÉTUDES MÉDICALES (V. E. M.).**—The nineteenth itinerary of the V. E. M. takes place from August 29th to Sept. 8th, Alsace-Lorraine and the Vosges being the districts visited. It has been organised by Dr. Maurice Gerst under the direction of Dr. Paul Carnot, professor of therapeutics in Paris, Dr. Harvier of the Hôpital Bicêtre assisting. In the course of the journey, which commences at Nancy, Strasbourg, Colmar, Plombières, Contrexéville, and Vittel will be visited, while opportunities will be given while at Nancy for an inspection of the battle-field of Verdun. The total cost for the expedition, which is restricted to doctors and senior medical students, has been fixed at Fr.1050 for travellers from countries where the exchange in high, and Fr.650 for participants where the exchange is low, these figures including all expenses—hotels, railway tickets, and motor-cars—from Nancy, the starting-point, to Vittel the place of disbandment; moreover, there will be a reduction of 50 per cent. to medical men and their wives on the French railways from the frontier to Nancy and back to the frontier from Vittel. British doctors desirous of participating should communicate with Madame Juppé-Blaise, representative of French spas, at the Office Français du Tourisme, 56, Haymarket, London, S.W.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 10TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 190 (last week 180); scarlet fever, 1483; diphtheria, 919; enteric fever, 45; pneumonia, 2074; puerperal fever, 57; cerebro-spinal fever, 7; acute poliomyelitis, 3; acute polio-encephalitis, 2; encephalitis lethargica, 47; dysentery, 6; ophthalmia neonatorum, 99. There were no cases of cholera, plague, or typhus fever notified during the week. The apparent increase in small-pox may be illusory, for this week and the last embraced the period of Easter when postal notification is impeded; the mean of the two weeks is below the figure of the previous week.

*Deaths.*—In the aggregate of great towns, including London, there were 6 (1) deaths from enteric fever, 100 (45) from measles, 6 (1) from scarlet fever, 55 (5) from whooping-cough, 45 (11) from diphtheria, 45 (12) from diarrhœa and enteritis under 2 years of age, and 204 (74) from influenza. The figures in parentheses are those for London itself. The notified deaths from influenza are 71 in excess of the previous week. The number of measles deaths has now reached 100 for eight weeks in succession.

## NOTES ON CURRENT TOPICS.

### THE ECONOMY BILL: MEDICAL BENEFIT.

ON Tuesday, April 13th, the House went into Committee on the Economy (Miscellaneous Provisions) Bill. Mr. JAMES HOPE was in the chair.

On Clause 2, which deals with the administration of medical benefit under the National Health Insurance Scheme,

Sir R. HAMILTON moved an amendment to reduce the sum of 3*d.* in respect of the expenses of the Minister to 1*d.*, which would mean, he said, a saving of about £120,000 to the societies. He understood that the actual expenses incurred by the Minister included 1*d.* per person for regional medical officers and the central committees. It had also been indicated that there were other costs to the approved societies in connexion with the printing of stamps which he understood had hitherto been a departmental charge. He should like to know whether this extra charge was also to be put on the approved societies. He thought the Committee ought to know what the charges actually amounted to, and whether the sum of 3*d.* was not considerably in excess of what was required.

Mr. N. CHAMBERLAIN (Minister of Health) said that in this question there were included only two kinds of expenditure. One was connected with the regional medical officers, and the other was the expense incurred in connexion with the central committees. The proposal to reduce the amount which might be paid to the Minister from 3*d.* to 1*d.* was based upon no logical foundation. It was not suggested by the hon. Member that 1*d.* would cover the cost of these two services, and what he was asking the Committee to do was to make a present to the approved societies of the difference between 3*d.* and 1*d.* and throw the portion of the charge which had hitherto rested on them on to the Exchequer. He could not accept the amendment.

Mr. J. H. THOMAS supported the amendment on the ground that it was an attempt to prevent the Government continuing their policy of bleeding the approved societies. Surely they had reached a stage when the Minister might make a concession.

After further discussion Mr. CHAMBERLAIN moved the closure, which was carried by 221 votes to 130. The amendment was then rejected by 220 votes to 142.

Mr. MACKINDER moved an amendment to postpone placing the cost of medical benefit on the approved societies until 1928. He said that a fortnight ago the Government had carried a proposal to rob the insurance fund of £2,800,000; now they were trying to put an extra cost on the approved societies of £2,000,000. The amendment would give the societies an opportunity to look round. One could argue—and he felt almost inclined to argue—that the position of the medical men was being made quite safe by Act of Parliament. He had taken part in the early negotiations when they tried to arrange terms with the doctors. They were now going to reach the magnificent sum of 12*s.* per year per member. He would like to go into other questions such as the drugs the doctors prescribed, but he feared it would be out of order to do so.

The Deputy Chairman (Captain FITZROY): I cannot see what this argument has to do with the question of postponement.

Mr. MACKINDER said he was trying to show the Committee that it was extremely wrong to give the doctors by Act of Parliament at least 12*s.* per year per member. At all events they ought to give the approved societies an opportunity of realising on a 12 months' experience what the effect of this Bill was going to be.

Mr. THOMAS was speaking in support of the amendment at 11 o'clock when, according to the rules of the House, the chairman left the chair to make his report to the House.

### *Health Insurance in the Services.*

On Wednesday, April 14th, the House considered on report a financial resolution in connexion with the Economy Bill, which enables the Government to appropriate the sum of £1,100,000 from the Navy, Army, and Air Force Insurance Fund. On the motion "that the House doth agree with the Committee in the said resolution,"

Mr. RAMSAY MACDONALD said that when he listened to the speech of the Secretary of State for War on the Committee stage, he really wondered if he were attending a meeting of the Soviets in Moscow. The arguments were exactly the same as one would expect to hear there when they were confiscating private property. The State was in need and the State in need dominated everything else. As a matter of fact, the country was in a peculiar position at the present time. It had got a Jacobin as Chancellor of the Exchequer, and as he wanted to balance his Budget he was adopting the principles of Lenin. He had persuaded the Minister of Health to take the position of Zinovieff, and he was asking the Secretary for War, who was doing his best, to fill the shoes of Mr. Trotsky. It was perfectly clear that if the Chancellor of the Exchequer had not been afraid to do it he would have invaded the actual surpluses of the approved societies. But here he was actually putting his hand into the pool and taking from it an accumulation of £1,100,000. There was absolutely no ground for doing this except the most miserable attempt to differentiate between this Fund and the funds of other approved societies, which could not be substantiated by anyone. Those who voted for the Government's proposal were going to declare that if the State found contracts inconvenient it could break them without even consulting the people with whom those contracts had been made.

Sir L. WORTHINGTON-EVANS (Secretary of State for War) said there was nothing in this measure which was in any sense at all a confiscation of property belonging to any individual whatever. This Fund was not an approved society; it was not managed by the members, and no member had any right of membership at all. It was a Fund created by the Government under an Act of Parliament for the purpose of providing benefits for those serving men who were unable to join approved societies. There were 23,000 entitled to benefit under this Fund. There were, as a matter of fact, about 160,000 serving men who were paying contributions, but only on an average 400 out of those who left the service every year joined this Fund because of their impaired health. The rest of them joined the friendly societies, and if the improvements, which were part of the Government plan to-day were fully carried out, they would go into those societies fully paid up without having to wait until they were entitled to benefit. This Fund was a Government guarantee of benefit, and the members were not entitled like members of approved societies to normal benefits and additional benefits. They were specifically prevented by Act of Parliament from having additional benefits at all. The actuary had certified that not merely the £1,100,000 which was being transferred, but the whole £1,500,000 was surplus to the requirements of the Fund—i.e., to pay the benefits to which the members were entitled. The surplus arose from the excessive contributions paid in by the Government in either one or other of its capacities. £400,000 was being set aside as a reserve against the liabilities for the additional benefits which the soldiers, sailors, and airmen were getting under these proposals—not the limited benefits to which they had been entitled in the past, but an additional benefit equal to the average of the approved societies. It was absurd, therefore, to talk about confiscation. It was done for party political purposes and with the obvious intention of creating dissatisfaction in the Forces of the Crown. The truth was that these men, far from being unfairly treated, were getting greater benefits under this Bill than were given to them by Mr. Lloyd George under the original Act.

After further discussion Sir L. WORTHINGTON-EVANS moved the closure which was carried by 240 votes to 144. The resolution was then agreed to.

The House then went into Committee on the Economy (Miscellaneous Provisions) Bill, and continued the discussion of Mr. Mackinder's amendment to Clause 2, which was interrupted on the previous evening.

Mr. N. CHAMBERLAIN (Minister of Health) said they had been told over and over again that this was an unjust charge in spite of the fact that the approved societies themselves, through the Consultative Council, recognised the justice of their meeting out of their funds the cost of medical benefit as well as other benefits. The position was really this. Under the main Act there was provided 9s. 6d. plus 6d., making 10s., as the cost of medical benefit and administration expenses. Now that would be entirely insufficient. It was necessary in 1924 to make some arrangement under which the difference between this 10s. and the actual cost of medical benefit and administration expenses should be met. There were negotiations and discussions between the Government and the approved societies. He understood that the approved societies were asked to meet this difference out of their benefit fund and they refused. Finally a way out was found by taking from the Unclaimed Stamps Sales Account certain moneys which were unused and utilising those moneys to make up a difference between the amount provided under the Act and the actual cost of the benefit and administration. That arrangement was embodied in an Act passed in 1924 called the Cost of Medical Benefit Act. Under that arrangement the full cost of those expenses had been met up to the present without making any charge on the Exchequer. Part of it had been provided out of the benefit funds, and the other out of these unclaimed stamps. The effect of postponing this clause would be that there would be no statutory provision for the difference between the cost and the 9s. 6d. and 6d. provided for in the Act of 1924. The amendment would mean that the whole scheme would come to an end. That was an impossible position. If hon. Members thought that they could continue to make up this difference out of the same fund which had hitherto made it good, he could assure them that that was not the case. The fund would be exhausted by the end of the year, and unless this clause was passed in its present form the whole scheme would be thrown into chaos and disorder and they would have to begin again and try to find some new arrangement.

After further discussion, Mr. CHAMBERLAIN moved the closure, which was carried by 215 votes to 180. Mr. Mackinder's amendment was then negatived by 241 votes to 144.

### *Allocation of the Composition Sum of 13s.*

On the motion that Clause 3 stand part of the Bill,

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health), replying to questions, said that there was a special provision for Scotland in Clause 2. In the sum of 13s. there were two items which particularly affected the sparsely populated areas of Scotland. One might be called the expenses for the mileage of doctors. In allocating the 13s., inasmuch as in Scotland the drug bill was less than in England, the clause allowed a special assistance to be given to medical men in particular areas in Scotland which were sparsely populated. That was over and above the amount given in England, and the necessary adjustments were made to keep it within the sum of 13s. This provision was put in at the request of the Scottish societies in order that further arrangements might be made with the medical men in that country to meet their special difficulties.

Mr. LLOYD GEORGE asked if the sum of 13s. under this clause represented the amount which the Minister of Health had decided should be paid to the doctors, or was it merely a maximum which had been put in for the purpose of complication without consulting the people who were primarily concerned at all and who had to pay it. On the other hand, if it was merely a figure to form the basis for negotiation, what folly to put in this sum at all! That was not a good way to start negotiations. He also wished to know whether the money which had been allocated to the Highlands of Scotland was money to which the Government were contributing 9d. in addition to what they were giving now, or whether on the contrary they would not be relieved of the part of the £3,800,000 to which they were contributing at the present moment.

Mr. N. CHAMBERLAIN said the sum of 13s. was a composition sum and included the composition fee which was the subject of agreement with the doctors; 9s. went to the doctors out of the 13s.

Mr. LLOYD GEORGE: What is the present amount of the composition sum?

Mr. N. CHAMBERLAIN: Ten shillings is the comparable amount, and the extra charge which comes out of the fund is the difference between 10s. and 13s. Continuing, the right hon. gentleman said that the 13s. was made up as follows: There was 9s. for the doctors, 4½d. for mileage charge, 2s. 9d. for drugs, 6d. for the expenses of the insurance committees, and 3d. for the Minister of Health in respect of regional medical officers and central administration. That made 12s. 10½d. There was a margin of 1½d. which was put in because, as was pointed out in the report of the Royal Commission, the cost of drugs had been rising in the past and there was no guarantee that they had reached finality in that respect. But it was provided in the proviso of Clause 2 that "if the aggregate sum paid for any year to insurance committees and the Minister under this section in respect of each of the total number aforesaid is less than the sum applicable as aforesaid in respect of each of the said total number, the balance shall be carried forward and be treated as being applicable as aforesaid in any subsequent year." So that nothing was lost if the margin was carried forward. It would be seen that this 13s. was nearly related to the actual cost of medical benefit, and was, in fact, a strict following of the recommendation of the Royal Commission, and while statements had been made as to the consent of the Consultative Committee to this proposal, the approved societies themselves did not consider that these benefits chargeable to the funds of the societies were in any way unreasonable.

Mr. WHEATLEY said that while the Minister of Health was very careful to shelter himself behind the recommendations of the Royal Commission when he was dealing with one part of the measure, he carefully ignored the fact that he was running directly contrary to the recommendations of the Commission in this particular section of the Bill which the Committee was discussing. He was heaping up expenses on the societies; he was diminishing the State contributions to the societies, and in that way he was preventing the societies from carrying out the policy of additional benefits, which was one of the main recommendations of the Royal Commission. Another thing which the right hon. gentleman carefully ignored was the fact that while certain interests, including the medical profession, were to get more, the whole of that additional expenditure was to come out of the pockets of the poor.

Mr. CHAMBERLAIN: Does the right hon. gentleman say that the medical profession are to get more in consequence of this clause? If so, that is a misunderstanding.

Mr. WHEATLEY: They are to get more than they would have got out of the old contributions to the societies.

Mr. CHAMBERLAIN: Not more than they are getting now.

Mr. WHEATLEY said that was so, but the sum which the doctors were getting now was the sum fixed while this matter was being discussed by the Royal Commission, and the settlement of this point was one of the things which gave rise to the appointment of the Commission. The doctors could not continue to receive the sum they were getting now out of the amount now being paid by the insured people, and therefore in order to save any reduction of the additional sum put on during the past two years for medical services, the right hon. gentleman took the other course and increased the amount to be paid by the insured people to a sum that would enable the demands of the other section to be met. This showed that they were taxing the poor to give additional remuneration to the medical profession. He was not arguing that the doctors were not entitled to the additional remuneration, nor that the 9s. capitation fee was too high, but he was arguing that it was unfair, when it was decided to increase the capitation fee, to include in the same provisions proposals not for an additional Government grant, but proposals to reduce the existing Government grant, which was based on a lower capitation fee than the one now being paid. That was a real injustice.

Mr. N. CHAMBERLAIN moved the closure, which was carried by 191 votes to 110. The clause was then added to the Bill by 118 votes to 114.

### *Making Good Deficiencies.*

On Clause 3 (which deals with the application of the Reserve Suspense Fund and Central Fund towards making good deficiencies due to the provisions of Part 1 of the Bill),

Mr. R. J. DAVIES moved an amendment to provide that the valuation of societies should take into account the necessary provision for continuing any additional benefits granted in respect of the surpluses of the first and second valuations. He said that the purpose of the amendment was to make sure that an approved society which had paid additional benefit as a result of the second valuation should not be in a worse position as a result of Clause 3 than it would have been if the clause had never been part of the Act. The clause provided that where a society was found on a certificate of the actuary to be in deficiency, that deficiency should be made up from a pool of surpluses of the other societies. Where a society had been giving, for the purposes of illustration, 2s. a week additional benefit for sickness, an additional 1s. for disablement benefit, and an additional 5s. for maternity benefit, besides dental treatment and dentures, and optical treatment and optical appliances, the amendment would enable the society to pay this additional benefit in spite of the provisions of this clause. It was agreed that, owing to Clauses 1 and 2, at least 10 per cent. of the societies would be in deficiency. That meant that 1,500,000 persons would suffer a deficiency through their approved societies.

Mr. N. CHAMBERLAIN said that he thought that Mr. Davies was not quite correct when he assumed that the societies representing 10 per cent. of insured persons who, as suggested by the actuaries, would be thrown into deficiency, would thereby be worse off. The provisions of this Bill were such that at any rate in some of those cases they would be no worse off. He would like to point out to the Committee what would be the effect of this amendment. Supposing that owing to some general cause the surpluses of all societies were reduced at the next valuation on account of an epidemic of disease, under the amendment there would be no claim on the fund from the careful society, but other societies which, through their laxity and carelessness might have brought down their surpluses on the third valuation, would immediately and automatically come in for a claim on the Reserve Suspense Fund. He did not think that this would be welcomed by the societies, and he could not accept the amendment.

Dr. DRUMMOND SHIELS said that it was rather alarming to find that the Minister of Health contemplated that after the third valuation a substantial number of societies might find it necessary to cut down the benefits given after the second valuation. It must be kept in mind that these additional benefits were not extra gifts, or something really outside the scope of the fund. They were simply an attempt to come a little nearer to the object of the insurance system. A full and complete medical service and adequate financial benefits were designed from the very first. Restrictions on these were principally made so that time might be given to show the financial soundness of the scheme, and how it had stood the strain of the war years. Now that these things had been assured it had naturally been expected, and the approved societies contemplated, bringing the scheme somewhat more into line with what was originally intended, and, therefore, these additional benefits which were being given as the result of the second valuation were not largess which might be taken away when circumstances were less propitious; they were steps on the road to a full realisation of a complete insurance scheme. The Minister's statement, therefore, would come as a very great surprise and shock to those who had been working the Act. It could not too often be emphasised that every penny which could be accumulated by this fund was required to make the scheme efficient, which at present it was not. For instance, no medical scheme could be successful that did not provide for efficient dental treatment. There was also the question of specialist medical benefit. In view of the enormous complexity of diseases and the great increase in specialist treatment nowadays, it was perfectly ridiculous to maintain a purely general practitioner's service for panel patients. He thought the least the Government could do was to say that in the event of a deficiency on the third valuation they would make up not only the minimum statutory benefits but any other benefits which might have been given, and to which the insured persons quite rightly thought they were entitled.

Mr. LLOYD GEORGE asked the Minister of Health whether he accepted the amendment in its present form or not to guarantee that through no action of the Government would there be any withdrawal of benefits already declared.

Mr. N. CHAMBERLAIN said that it was much too soon to be able to say what they would be able to do in 1931. The actuaries were themselves unable to say. But what they did know was that while there was a reduction in the State contribution there were also various other factors, such as the rate of interest, the increasing amount and proportion of the societies' funds on which that rate of interest was earned, and the increasing number of contributors that might be expected each year. But the surpluses must fluctuate. It was therefore asking something that had never been contemplated to ask that additional benefits should be in the same position as if they were statutory benefits.

After further discussion the closure was carried by 162 votes to 104. The amendment was then negatived by 163 votes to 106.

Clause 3 was added to the Bill by 163 votes to 105.

Clause 4 of the Bill amends Section 68 of the principal Act. Para. (*b*) of Subsection 2 of the clause deals with the appropriation of certain sums for defraying such proportion as is not derived from moneys provided by Parliament of any liability outstanding on Dec. 31st, 1926 (after exhausting all sums applicable thereto under Section 1 of the National Health Insurance (Cost of Medical Benefit) Act, 1924), in respect of the cost of drugs, medicines, and appliances supplied as part of medical benefit.

After debate the clause was added to the Bill by 155 votes to 83. Progress was reported.

### *Health Insurance in the Services—(continued).*

On Thursday, April 15th, the House went into Committee on the Economy Bill, Mr. JAMES HOPE in the chair.

On Clause 5 (which deals with the transfer to the Exchequer from the Navy, Army, and Air Force Insurance Fund, constituted under the principal Act, of £1,100,000),

Mr. RICHARDSON moved to leave out Subsection (1), which transfers the sum of £1,100,000 from the fund to the Exchequer.

Dr. VERNON DAVIES said that the supporters of the Government had listened to many criticisms of this Bill, and they had been accused of cowardice for not speaking in support of it. The Opposition were wrong in thinking that they had remained quiet because they were not willing to support the Government, or because the Opposition's arguments had convinced them. He thought that the Government were acting honestly and seriously in this matter. But he hoped that the Secretary for War would pass on to the Chancellor of the Exchequer the suggestion that there was a crying need in the Service for some of this money. He referred particularly to the question of tuberculosis, which in the Services was at present an extremely urgent one. The medical authorities decided whether tuberculosis was attributable to the conditions of service or not, and as far as he could make out there was no appeal against their decisions. Consumption was caused by a bacillus which everyone was breathing in every day of his life. They did not get consumption and die from it, because the condition of their bodies was such that they were able to resist the germ. But no doctor, whether in the Navy, Army, or Air Service, was in a position when a man had contracted consumption to guarantee that it was attributable to the conditions of his service or not. It was only a guess, though it might be a very good guess.
